A MEDICAL JOURNAL CONTAINING

THE OFFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ
THE ANNUAL SESSION, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY

GEORGE H. SIMMONS, M.D.

VOLUME LI. : : : : : : JULY—DECEMBER, 1908

AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1908

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1908-1909.

GENERAL OFFICERS

PRESIDENT—HERBERT L. BURRELL	Boston.
PRESIDENT-ELECT—WILLIAM C. GORGAS	Ancon, Panama.
FIRST VICE-PRESIDENT—T. J. MURRAY	Butte, Mont.
SECOND VICE-PRESIDENT—J. A. HATCHETT	El Reno, Okla.
THIRD VICE-PRESIDENT—T. A. WOODRUFF	Chicago.
FOURTH VICE-PRESIDENT—E. N. HALL	Woodburn, Ky.
GENERAL SECRETARY—GEORGE H. SIMMONS	103 Dearborn Avenue, Chicago.
TREASURER—FRANK BILLINGS	Chicago.

BOARD OF TRUSTEES.

William H. Welch, Chairman	Baltimore, 1909.
Miles F. Porter	Fort Wayne, Ind., 1909.
M. L. Harris, Secretary	Chicago, 1909.
T. J. Happel	Trenton, Tenn., 1910.
W. W. Grant, Vice-Chairman	Denver, 1910.
Philip Marvel	Atlantic City, 1910.
Wisner R. Townsend	New York, 1911.
Philip Mills Jones	San Francisco, 1911.
W. T. Sarles	Sparta, Wis., 1911.

JUDICIAL COUNCIL.

C. E. Cantrell, Chairman	Greenville, Texas.
R. C. Cabot	Boston.
G. W. Guthrie	Wilkes-Barre, Pa.
Thomas McDavitt	St. Paul, Minn.
Charles J. Kipp	Newark, N. J.

COUNCIL ON MEDICAL EDUCATION.

Arthur Dean Bevan, Chairman	Chicago.
W. T. Councilman	Boston.
Victor C. Vaughan	Ann Arbor, Mich.
J. A. Witherspoon	Nashville, Tenn.
James W. Holland	Philadelphia.

COUNCIL ON PHARMACY AND CHEMISTRY.

J. A. Capps	Chicago.
D. L. Edsall	Philadelphia.
Otto Folin	Boston.
C. S. N. Hallberg	Chicago.
R. A. Hatcher	New York City.
Reid Hunt	Washington, D. C.
L. F. Kebler	Washington, D. C.
J. H. Long	Chicago.
F. G. Novy	Ann Arbor, Mich.
W. A. Puckner, Secretary	Chicago.
J. O. Schlotterbeck	Ann Arbor, Mich.
George H. Simmons, Chairman	Chicago.
Torald Sollmann	Cleveland.
Julius Stieglitz	Chicago.
M. I. Wilbert	Philadelphia.
H. W. Wiley	Washington, D. C.

BUREAU OF MEDICAL EDUCATION.

Charles A. L. Reed, Chairman	Cincinnati.
C. S. Bacon	Chicago.
Charles Harrington	Boston.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Joseph L. Miller, 100 State St., Chicago; Secretary, Wilder Tileston, 311 Beacon St., Boston. Executive Committee—Herbert C. Moffitt, San Francisco; Thomas D. Coleman, Atlanta, Ga.; C. F. Hoover, Cleveland.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, W. P. Manton, 32 Adams Ave., W., Detroit; Vice-Chairman, H. G. Wetherill, Denver; Secretary, C. Jeff Miller, 124 Baronne St., New Orleans. Executive Committee—C. S. Bacon, Chicago; J. Wesley Bovée, Washington, D. C.; W. B. Dorsett, St. Louis.

SURGERY AND ANATOMY—Chairman, John C. Munro, 173 Beacon St., Boston; Vice-Chairman, J. E. Summers, Omaha; Secretary, John F. Binnie, Argyle Building, Kansas City, Mo. Executive Committee—Robert F. Weir, New York City; Arthur D. Bevan, Chicago; Rudolph Matas, New Orleans.

HYGIENE AND SANITARY SCIENCE—Chairman, Joseph H. White, P. H. and M.-H. Service, 609 Canal-Louisiana Bldg., New Orleans; Vice-Chairman, J. N. Hurty, Indianapolis; Secretary, S. T. Armstrong, 144 East 37th St., New York City. Executive Committee—Denslow Lewis, Chicago; Prince A. Morrow, New York City; William C. Gorgas, Ancon, Panama.

OPHTHALMOLOGY—Chairman, Alvin A. Hubbell, 212 Franklin St., Buffalo; Vice-Chairman, Melville Black, Denver; Secretary, Albert E. Bulson, Jr., Fort Wayne, Ind. Executive Committee—Lewis H. Taylor, Wilkes-Barre, Pa.; G. C. Savage, Nashville, Tenn.; Wm. H. Wilder, Chicago.

DISEASES OF CHILDREN—Chairman, Thomas S. Southworth, 807 Madison Ave., New York City; Vice-Chairman, C. F. Wahrer, Fort Madison, Iowa; Secretary, W. W. Butterworth, 609 Macheca Building, New Orleans. Executive Committee—W. C. Hollopeter, Philadelphia; J. Ross Snyder, Birmingham, Ala.; E. E. Graham, Philadelphia.

STOMATOLOGY—Chairman, Edward C. Briggs, 129 Marlboro St., Boston; Vice-Chairman, Thomas L. Gilmer, Chicago; Secretary, Eugene S. Talbot, 103 State St., Chicago. Executive Committee—H. P. Carlton, San Francisco; M. I. Schamberg, New York City; E. A. Bogue, New York City.

NERVOUS AND MENTAL DISEASES—Chairman, M. Allen Starr, 5 West 54th St., New York City; Secretary, Wm. Alexander Jones, Pillsbury Building, Minneapolis. Executive Committee—Wharton Sinkler, Philadelphia; Morton Prince, Boston; T. H. Weisenburg, Philadelphia.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Wm. Allen Pusey, 72 E. Madison St., Chicago; Vice-Chairman, Grover W. Wende, Buffalo; Secretary, M. L. Heidingsfeld, 19 West 7th St., Cincinnati. Executive Committee—Douglas W. Montgomery, San Francisco; R. R. Campbell, Chicago; M. B. Hartzell, Philadelphia.

LARYNGOLOGY AND OTOLOGY—Chairman, W. Sohier Bryant, 57 West 53d St., New York City; Vice-Chairman, B. R. Shurly, Detroit; Secretary, Geo. E. Shambaugh, 100 State St., Chicago. Executive Committee—Otto T. Freer, Chicago; S. MacCuen Smith, Philadelphia; H. W. Loeb, St. Louis.

PHARMACOLOGY AND THERAPEUTICS—Chairman, Reid Hunt, 25th and E Sts., N.-W., Washington, D. C.; Vice-Chairman, W. W. Tompkins, Charleston, W. Va.; Secretary, C. S. N. Hallberg, 36 Twelfth St., Chicago. Executive Committee—Thomas P. Reilly, New York City; H. C. Wood, Jr., Philadelphia; M. H. Fussell, Philadelphia.

PATHOLOGY AND PHYSIOLOGY—Chairman, M. J. Rosenau, 25th and E Sts., N.-W., Washington, D. C.; Secretary, H. Gideon Wells, 6025 Kimbark Ave., Chicago. Executive Committee—Henry A. Christian, Boston; Walter L. Bierring, Iowa City, Iowa; W. B. Cannon, Boston.

"The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions or criticisms therein contained, except when otherwise decided by special resolution."—TRANSACTIONS, 1851.

Addresses

NEUROLOGIC TEACHING IN AMERICA.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON NERVOUS AND MENTAL DISEASES, CHICAGO, 1908.

T. H. WEISENBURG, M.D.
Professor of Neuropathology and Associate Professor of Neurology, Medico-Chirurgical College, Neurologist to the Philadelphia General Hospital.
PHILADELPHIA.

HISTORICAL.

A more brilliant exponent of the teaching of neurology and psychiatry than Benjamin Rush, who in the latter part of the eighteenth century first inaugurated such instruction in this country, would have been difficult to select. In a lecture on "The Necessary Connexion Between Observation and Reasoning in Medicine," delivered Nov. 7, 1791, before the medical students of the University of Pennsylvania, Dr. Rush outlined a course of lectures which he was about to give. He divided the institutes of medicine into physiology, pathology and therapeutics. Under physiology he stated: "I shall include the faculties of the mind in this part of our course and shall endeavor to explain their operation in a manner so simple as to make them intelligible to the youngest student of medicine."

A syllabus of these lectures, with the additions which became necessary after the author undertook to teach the practice of medicine, was subjoined to this lecture.

Under the head of physiology, among other divisions, he has that of the nervous system in which are included the offices of the brain, nerves and muscles, and under faculties and operations of the mind he takes up its subdivisions, such as instinct, memory, imagination, understanding, will, passions, emotions, faith, etc.

Under practice of medicine he discusses "the diseases as they appear in the blood vessels and nervous system, in the latter of which are included the nerves, muscles, brain and mind, and the alimentary canal predominating in each of them more or less according to circumstances."

It will be seen from the above that Rush was in the habit of discussing at length in his medical lectures the nature and phenomena of diseases of the mind and of the nervous system. Doubtless his work on "Diseases of the Mind," which was first published only a few months before his death, was the ripe fruit not only of years of study and observation, but also of teaching. This treatise was the fifth volume of his principal works in seven volumes, which is entitled "Medical Inquiries and Observations on Diseases of the Mind," and appeared first in 1812, passing through several editions.

It would hardly seem necessary at this time to emphasize again the important place in the history of medicine occupied by Benjamin Rush were it not for the fact that, so far as I know, after his death in 1813 and until 1870, a period of fifty-seven years, no systematic teaching in psychiatry was attempted in any medical school in this country. Not only that; but his work on psychiatry was the only systematic American treatise on this subject until the year 1883, when William A. Hammond and C. E. Spitzka and later E. C. Mann published text-books on insanity.

FIRST LECTURESHIP ON NERVOUS DISEASES.

Doubtless diseases of the nervous system as distinctive from diseases of the mind were taught from the time of Benjamin Rush under the head of practice of medicine. It was not, however, until 1867 that the first distinctive lectureship on diseases of the nervous system was established in the Bellevue Medical College in New York City. In that year Dr. William A. Hammond first taught this subject. This distinguished physician after having been Surgeon-General in the United States Army went to New York and soon after his arrival became interested in editorial work, and for five years, beginning with 1867, he edited the *Quarterly Journal of Psychological and Medical Jurisprudence.* Later he also edited the *New York Medical Journal* and the *Journal of Nervous and Mental Disease.* He was appointed professor of nervous and mental diseases in the Bellevue Hospital Medical College in 1867, this probably being the first professorship in nervous diseases held in this country. He taught there for six years and in the University Medical College for nine years more. In 1871 the first edition of his book on nervous diseases appeared. Although it was a complete treatise, it was published as a second volume to "A Treatise on the Physiology and Pathology of the Nervous System," the fourth volume of Dr. Austin Flint's "System of Physiology" forming Volume I. The first edition was soon exhausted, and a second was put out without reference to the volume on physiology. This was the first distinctive book on diseases of the nervous system by any American writer and found such favor that it was translated into most of the foreign languages.

A year later a lectureship on diseases of the nervous system was established in the College of Physicians and Surgeons, New York City, now the medical department of the Columbia University. The first lectures were given by Dr. E. C. Seguin during the summer session of 1868, and the first clinic for diseases of the nervous system was announced in 1874 and was given by Dr. Seguin. This was the beginning of clinical teaching in New York City. He was succeeded by Dr. M. Allen Starr, who still holds the position.

About this time, that is, in 1864, Dr. J. Hughlings Jackson made his memorable suggestions that movements of the various parts of the body are controlled by special convolutions, and in 1868 he first applied the principles of evolution and dissolution to the study of language. It was undoubtedly through the enthusiasm created by the work of this master, combined with the researches of Hitzig, Fritsch, Ferrier and later of Charcot, that diseases of the nervous system gained an additional and renewed importance, and from this time began a new era in neurology.

THE FIRST NEUROLOGIC PAPERS.

In America the first neurologic papers appeared between 1864 and 1874 when Dr. S. Weir Mitchell, of Philadelphia, published a number of important contributions to neurology, the first being his celebrated work on "Injuries of Nerves," in collaboration with Morehouse and Keen; while in 1874 Dr. J. J. Putnam, of Boston, with the assistance of Drs. Bowditch and James, experimented with faradic currents on the cortex and subcortex.

Following the lead of the Bellevue Medical College and the College of Physicians and Surgeons of New York, other medical schools soon fell in line. In 1871 Dr. H. C. Wood was appointed lecturer on nervous diseases in the University of Pennsylvania and in 1873 he was made clinical professor.

In the West, Dr. J. S. Jewell was appointed in 1872 professor of nervous and mental diseases in the Chicago Medical School, now the Medical Department of Northwestern University. Dr. Jewell took a leading part in organizing the American Neurological Association, and was not only its first president, but occupied that honored position for five years. As a matter of history it is interesting to record that Dr. S. Weir Mitchell was elected the first president and Dr. Jewell the first vice-president, but for personal reasons Dr. Mitchell declined to serve and Dr. Jewell became the first president. Dr. Jewell also in 1875 founded the *Journal of Nervous and Mental Disease.*

In Boston, Dr. J. J. Putnam was first made lecturer in neurology in 1872 at Harvard University, and after occupying various positions was made professor of diseases of the nervous system in 1893, when the department of neurology was made separate.

BEGINNING OF SYSTEMATIC INSTRUCTION.

Although from this time on professorships in neurology were established in nearly all the medical schools, it was not until within a few years that systematic teaching was attempted, for, curious as it may seem, although the general medical public, as a rule, recognizes the importance of neurology as a distinct branch, in some of the medical schools neurology is still regarded as part of the general course in medicine. In Harvard, for instance, it was made a separate department in 1893, while in the University of Pennsylvania it was not until shortly after 1901, when Dr. Charles K. Mills was made clinical professor of nervous diseases, that the department of neurology became separate from that of medicine, and this subject was for the first time taught entirely by its members. It was also at this time that systematic ward class teaching was first instituted.

The teaching of neurology was not confined exclusively to the medical schools, for in various nervous clinics and hospitals which were established in different parts of the country independent neurologic teaching was done. Among the best known of these, and probably the first neurologic clinic in this country, was the Orthopedic Hospital in Philadelphia, which was established in October, 1867, the neurologic department of which, designated as the infirmary for nervous diseases, being opened in 1870 with Dr. S. Weir Mitchell in charge and Dr. Wharton Sinkler and others as assistants. The out-patient department in this clinic is enormous, and here such well-known men as Drs. S. Weir Mitchell, Wharton Sinkler, Morris J. Lewis, J. K. Mitchell and others taught and are still teaching. It was from this clinic that Dr. S. Weir Mitchell published his "Clinical Lessons."

ESTABLISHMENT OF NERVOUS WARDS.

No American neurologic history would be complete without some reference to the nervous wards of the Philadelphia Hospital, which were established in 1877 through the energy and far-sightedness of Dr. Charles K. Mills. These wards which had thirty-five patients in 1878 now have on an average about four hundred organic nervous cases, this being undoubtedly the best collection of nervous material in any one hospital in America and possibly the equal of any abroad. From 1877 patients from these wards have been used for clinical teaching, first by Dr. Mills and later by such men as Wood, Bartholow, Dercum, Lloyd, Sinkler, Burr and others.

Electro-therapeutics as a department of neurology began to be taught about the year 1875 by Neftell and Beard and Rockwell, of New York. Beard and Rockwell were the first to write a book on this subject, it being entitled "A Treatise on the Medical and Surgical Uses of Electricity," published in 1881. In Philadelphia Dr. Charles K. Mills was appoited lecturer on electro-therapeutics in the University of Pennsylvania in 1877.

Neuropathology as a distinctive branch and under that name was taught by Dr. E. W. Taylor, of Boston, in the spring of 1891 in Harvard University, although this subject was undoubtedly taught previously under the head of pathology. Dr. William G. Spiller was the second to teach neuropathology, he being appointed assistant professor of neuropathology in the University of Pennsylvania in 1901 and in 1903 full professor. Since then similar positions have been created in Harvard, the Medico-Chirurgical College of Philadelphia and elsewhere.

Before discussing the present methods of teaching neurology, it might be well to briefly review the history of the teaching of psychiatry. After Benjamin Rush there were no lecturers on insanity until 1867, when Dr. William A. Hammond taught in the Bellevue Hospital Medical College, and following him Dr. E. C. Seguin in the College of Physicians and Surgeons of New York in 1871.

In Philadelphia psychiatry was not taught until 1870, when Dr. Isaac Ray was appointed lecturer on insanity in the Jefferson Medical College of Philadelphia. He taught during the spring sessions of 1870-1872 During the time that he was engaged in lecturing and partly with the view of illustrating his remarks Dr. D. D. Richardson, then superintendent of the insane department of the Philadelphia Hospital, gave clinical demonstrations on insanity to students at the hospital. Not only was Dr. Ray one of the earliest physicians in the United States to follow the example of Rush and pay special attention to the study of psychiatry, but he was the first to write a book on the "Medical Jurisprudence of Insanity," it being published in Boston in 1838. After him Dr. Charles K.

Mills taught psychiatry in the University of Pennsylvania, being appointed lecturer on mental diseases 1881 and being later made professor of mental diseases and of medical jurisprudence in 1893. In Boston the first teaching was done by Dr. C. F. Folsom, who lectured on mental diseases in Harvard University in 1877.

In discussing the methods now employed in teaching neurology in the medical schools of America, it will be manifestly impossible to review all; consequently only four have been selected, these being the medical departments of Harvard, Cornell, Pennsylvania and Northwestern universities. Attention, however, has also been paid to the methods of other schools, chiefly of Columbia and Bellevue of New York, Jefferson and the Medico-Chirurgical in Philadelphia, Johns Hopkins, Baltimore, and Rush Medical College in Chicago, the courses in which do not differ radically from those in the four institutions selected for analysis.

METHODS AT HARVARD.

Perhaps the most elaborate course in both nervous and mental diseases is given in Harvard. Here the department of neurology has been separate since 1893, although psychiatry until last year formed a part of the department of theory and practice. Neuropathology became separate a year ago, but is in close affiliation with both the pathologic and neurologic departments. Neurologic teaching begins in the second year, with a course in neuropathology for a period of three weeks, occupying each afternoon. This time is given to a lecture, or talk, of an hour explanatory of microscopic sections and two hours is given to laboratory work. Lantern slides are freely used. In addition to these required exercises two or three quizzes are given of a wholly voluntary character in which anatomic considerations are reviewed. These lectures are preparatory not only for the study of neurology, but also in part for that of psychiatry, while the laboratory work aims, so far as possible, to fit the student to better appreciate clinical work and to complete his knowledge of pathology. An optional course is also given in applied psychology.

In the third year the student receives one clinical lecture a week in neurology during the first term and two during the second. These lectures are made as informal as possible and deserve rather the name of conferences. Besides, two exercises a week are given in psychiatry throughout the whole of the second term. One of these exercises consists in a lecture and the other in a clinical demonstration in an insane hospital.

The fourth year is given up largely to elective courses and the students who elect neurology and psychiatry spend nominally about two hundred hours in practical work in the out-patient department of the general hospitals. In detail the classes consist of about five men each and each class has two months' teaching, during which they spend three forenoons a week in neurology and two in psychiatry. As a part of this course the students receive some special instruction in neuropathology and also have a weekly evening conference. Besides, there is an elective course in the department of neuropathology. This consists either of all day teaching for a single month or half a day for two months. The method of instruction is elastic and varies with the desires and preparedness of the individual student. The teachnical methods of neuropathology are taught and sometimes a neuropathologic problem is given.

NEUROLOGY AT CORNELL AND NORTHWESTERN UNIVERSITIES.

In Cornell University, the neurologic department is distinct from the department of psychiatry. The second-year students are taught the normal and pathologic histology of the nervous system in a laboratory course of six weeks. In the third year a course of thirty-two clinical lectures is given, and the students are divided into classes of twelve, each of which has twelve hours of practical work in the dispensary. In the fourth year twenty-four clinical lectures are held and the classes are divided into sections, each having six hours of bedside instruction in the hospital wards. Psychiatry is taught by lectures, clinics, reviews and optional section work in the fourth year.

In Northwestern University all the neuropathologic work is under the department of pathology. In the third year neurology is taught by recitation only. In the fourth year didactic lectures are given once a week for the first half of the year on nervous diseases and in the second half in psychiatry. Besides one clinical lecture a week on nervous diseases is held throughout the whole year. The students are also divided into dispensary classes of twenty, each having two hours daily for four weeks, and are also divided into small classes for ward walks.

INSTRUCTION AT UNIVERSITY OF PENNSYLVANIA.

In the University of Pennsylvania instruction begins in the third year, the men being given a course in neuropathology, each man having one hour a week for the first half of the term. First, gross specimens are shown, and later lantern demonstrations illustrative of the different diseases. In the fourth year two clinical lectures are held for the first half of the term and one in the second half. The students are also divided into classes of ten, each man receiving ward instruction weekly for the first half of the session. In addition the students in small classes have as part of the course what are termed ward visits in which particular attention is paid to the method of recording as well as studying cases. Psychiatry is taught by the professor of mental diseases who gives one clinical lecture a week in the first half of the fourth year.

In reviewing the methods employed in these four schools it will be seen that in all, with the exception of Harvard, instruction is somewhat alike, in so far as the fourth year is concerned. Clinical lectures are given both in neurology and psychiatry, and ward classes are held either in one-half or throughout the entire year. In the third year in the Northwestern University recitations only are used, in the University of Pennsylvania neuropathology only is given, while in Cornell both clinical lectures and ward classes are held. In the second year there is no direct neurologic instruction with the exception that in the course of pathology reference is made to the nervous system. In Harvard pathology is taught in the second year, clinical lectures on nervous and mental diseases are given in the third, whereas in the fourth year it is optional with the student whether he elects neurology and psychiatry.

TEACHING NEUROLOGY IN EUROPE.

It is interesting to compare the methods employed in this country with those of the leading schools of Europe, although comparisons are rather difficult to make because the methods of medical teaching are so different.

In Vienna, for instance, the students are required to devote one semester each to clinical neurology and psychiatry. These consist of five clinical lectures each week, one hour in duration, and the student may take these during the seventh, eighth or ninth semesters, as he prefers. Neuropathology as a distinct branch is considered extra work and is not a required part of the curriculum.

In Paris neurologic teaching is not conducted systematically, but is divided among the departments of anatomy, physiology, pathology and clinical medicine. In addition courses are given by the professor of diseases of the nervous system and the professor of psychiatry, these consisting of clinical lectures in the various hospitals and clinics. No systematic teaching is attempted, however, and each professor lectures on those topics which interest him. Ward class teaching, as it is known in America, is not given to the undergraduate student, and neuropathology is considered a postgraduate study.

In England neurology is taught as a part of general medicine. In the London Hospital, for instance, Dr. Head, being interested in nervous diseases, has more neurologic patients in his beds than the other physicians and he lectures on these cases every week and gives definite teaching in neurology, and any student, whatever his standing, can attend. In the physiologic class, instruction is given in the structure and functions of the nervous system, and in the class in pathology specimens are shown illustrating nervous cases.

It will be seen, then, in comparison, that is, so far as systematic teaching of neurology to undergraduates is concerned, the American schools are by far in the lead, especially of those in France and England, and possibly of those in Germany and Austria. Whether the results are as good or better is difficult to tell because the course of study abroad is longer, and again no adequate comparisons are possible.

POSTGRADUATE INSTRUCTION IN AMERICA.

Postgraduate medical instruction in this country has not received the attention that it has abroad. The first postgraduate school was the New York Polyclinic, established in 1881. A year later the Postgraduate School was established in New York and the Polyclinic in Philadelphia. Here the students are taught in the outpatient departments of the attached hospitals and cases are demonstrated, but no systematic teaching is attempted. In Harvard a postgraduate course is given, this practically consisting in the fourth-year undergraduate instruction.

An essay of this kind would hardly be complete without some effort being made to outline a course which would be peculiarly fitted to the needs of the American medical student.' From the experience of others and also from my own experience it is rather questionable whether it is possible to give a satisfactory course in the limited hours assigned to neurology and psychiatry in a four-year course. Paradoxical as it may seem, neurology has not received attention in the curricula in some of the leading medical schools equal to that of some of the other specialties, as, for instance, the eye. There is no need of discussing here the importance of teaching the student more of nervous and mental diseases, for that is evident, and yet even at the present time neurology receives such little attention that in most of the medical schools those who hold neurologic professorships are not members of the major faculty. Not only that, but in some of the schools a separate examination is not given by the professor of the department. In still a number of others the lectures are given by the professor of medicine, while the clinical lectures are held by the professors of nervous and mental diseases.

In the first place, when considering the nature of our medical students and the methods of our teaching, it is a matter of universal experience that students will not pay much attention to a subject in which there is no required examination. Not only should an examination be held in neurology, but it should also be held in psychiatry. At the present time lectures are given in mental diseases, and it is optional with the student whether he attends and no examination is given, at least that is the rule in most of the medical schools.

Of course, it is taken for granted that the student who graduates at a four years' course can only have a general knowledge of the specialties, and it is not to be thought for a moment that any effort should be made to make him a specialist. The best that should be attempted is to give him a good course in the principles of the anatomy, physiology and pathology of the nervous system and to teach him how to recognize the more important nervous and mental diseases and how to treat them.

GENERAL NEUROPATHOLOGY NOT A SPECIAL BRANCH.

It is rather questionable whether general neuropathology should be taught as a distinct branch. My personal views are that the general pathology of the nervous system should be taught as part of the regular course in pathology and that it should be given in the second year by a specially trained neuropathologist. After all, the pathologic changes in the nervous system are not so very different from those in any of the other organs of the body, and a course consisting of two or three hours daily for a period of three weeks will fully cover the subject. It is advisable in this course to teach the student only the more important stains and general pathologic changes so that he should be prepared to appreciate further instruction. The special pathology of the different diseases of the nervous system should be taught later.

It is a good plan to begin the third year by a course in terminology. Then the student should be instructed in the ordinary clinical signs, such as reflexes, the different tests for sensation, gait, station, etc. In other words, he should be given a clinical demonstration of the ordinary signs employed in nervous diseases and their meaning. After this it is advisable to take up serially the teaching of what could be called applied anatomy and physiology.

A METHOD SUGGESTED.

By that I mean, for instance, this: A brain is shown and the different fissures and convolutions outlined. Then starting, for instance, with the motor centers, the physiologic subdivisions of the precentral convolution are given and the students told what irritative and then what destructive lesions will produce. An ideal plan would be, if such a thing is possible, to show a patient illustrative of the subject, but this is hardly feasible. If this plan is continued, the anatomy, physiology and pathology of the brain can be taken up in serial order, first of the cortex, then the subcortex, internal capsule, crus, pons, medulla and later of the spinal cord, illustrating the whole course with pathologic specimens and lantern slides both of normal and then of pathologic specimens. This subject can be thus covered in the first half of the term with two hours a week.

In the second half of the term the different diseases then can be taken up in serial order and the symptoms taught, applying the knowledge gained from the instruction in the previous term. The pathology of the more common mental diseases should be included. In conjunction with this course the student should attend the clinical lectures on nervous diseases which are primarily held for the fourth-year men, and, if possible, ward classes should be given in the second half of the term or throughout the entire year, so that the student should be able to fix more definitely the didactic instruction received.

In the fourth year the primary object of the teaching should be to show as many clinical cases as possible and to teach the student to reason the pathology from the clinical symptoms. It is questionable which is the better method of teaching, that is, whether it is advisable to take up a certain given subject like hemiplegia and devote one-half of the lecture to the didactic exposition of the symptoms and then to illustrate by the cases, or to show patients immediately, making the remarks depend on the individual case. My own views are that the first plan is the better. If this plan is followed, the more common diseases can be taught first and toward the latter end of the year the rarer cases can be taken up.

There should be at least one clinical lecture a week, and if possible two, throughout the entire year. Besides, the class should be divided into groups of no more than ten and taught either in the out-patient department of a hospital or in special nervous wards.

Each student should receive at least one hour a week throughout the entire year. In conjunction with this, if there is time and material, it would be a good plan to place each student in charge of a certain number of cases in the wards of a hospital and make him responsible in a manner similar to that of a resident physician.

Psychiatry should be taught throughout the entire fourth year. It would be a good plan to first give a short didactic course, to be followed by clinical lectures. Here, also, it should be advisable to divide the class into sections and give personal instruction in the wards of an insane hospital.

The course that is herein laid out is one that is followed with few exceptions in the Medico-Chirurgical College.

The exceptions are that no ward classes are held in the third year in nervous diseases and none in psychiatry in the fourth year. In the present scramble for more teaching hours, a subject of the utmost importance to every one connected with medical institutions, it is evident that we are coming to a time when it is impossible to crowd more hours into the curriculum of the already overworked student, and it is imperative that the course should be lengthened with an additional year.

This has been recognized by most medical institutions, and it is only a question of a few years when such a step will have to be taken, for with the increased entrance requirements and demands made on the graduate it is necessary that he should not only be more proficient in the fields of general medicine and surgery, but that he should also be better equipped in the specialties.

2030 Chestnut Street.

DISCUSSION.

Dr. Charles E. Beevor, London, Eng., said that in England there was no special course of *instruction on diseases of the* nervous system. Diseases of the mind were separated from diseases of the nervous system, and there was a special course on diseases of the mind. Diseases of the nervous system, however, were considered as properly embraced in the student's study of general medicine, and no more properly subjects for special instruction than diseases of the lungs, kidneys or other part of the body. Dr. Beevor said that in every hospital in London there was always in charge of all the nervous cases one physician especially interested in nervous diseases. This physician showed the students pathologic subjects and really taught them just as students were instructed in the hospitals here. The intention, however, was to produce good general all-round practitioners.

Dr. Beevor explained that the English student, after completing his course, came around to special hospitals and then to a hospital like National Hospital of Queen's Square, there meeting and studying nervous diseases; or he might come to the hospital before finishing his undergraduate course. He thought that perhaps they did not specialize quite as much in nervous diseases in London as in other countries. At the National Hospital, Queen's Square, almost every physician was also a physician in the general hospital. Dr. Beevor said that he himself, besides being in the National Hospital, was also physician at the Great Northern Hospital, where he saw cases of rheumatism, typhoid, pneumonia, and in fact all general medical cases and he believed that this was a good thing.

Dr. Beevor thought that, if the neurologist saw nothing but nervous cases, he was led to view everything through neurologic spectacles. The daily sight of cases of pneumonia and rheumatic fever would prevent that mistake. He said that the general practitioner often referred to the specialist a case of miscalled nervous disease. Dr. Beevor instanced three such cases which had been brought to him. The general practitioner had made the erroneous diagnosis of melancholia. Another was called paraplegia in a patient with gangrene of the foot. That was very rare in connection with nervous disease. Examination developed a thickening of the bone at the brim of the pelvis which accounted for the pressure on the artery and for the gangrene. The person had a large clavicle, a large humerus, and was suffering from osteitis deformans.

The third case had been brought to him as a case of cerebral tumor. The patient suffered from heavy vomiting and possible neuritis. Dr. Beevor examined the patient and found cardiac hypertrophy and high tension pulse. The general practitioner did not know whether there was any albumin present or not. Dr. Beevor asked leave to examine for it and found albumin. That was evidence of granular kidney, and none of tumor of the brain at all. Dr. Beevor added that the patient did not believe him because he was a nerve specialist, and went to a general physician to have the diagnosis confirmed.

Dr. M. Allen Starr, New York City, said that it seemed to him that the profession was confronted with two alternatives: Was the average medical student to be given a fair general knowledge of neurology such as would enable him to do his work in the world as a general practitioner, or the careful, differential training of a specialist? The first, he said, was the endeavor of the College of Physicians and Surgeons; the second was what Harvard University was trying to accomplish by the optional or elective course. Dr. Starr thought that the English method as detailed by Dr. Beevor was, perhaps on the whole, the better for the general practitioner and that medical education was bound to produce well-rounded medical students and not specialists. He thought that the finer special line of work obtainable in Germany in the special clinics, or in England at the National Hospital at Queen's Square could not be given in this country.

Dr. F. X. Dercum, Philadelphia, said that specialists had forced medical schools to give undue attention to the specialties. When he was first given an examination in neurology at Jefferson Medical College, his average had counted 100, the same as in internal medicine. Now it counted 40, which Dr.

Dercum thought an improvement and not a lowering at all in the importance of neurology. He said that the students at Jefferson Medical College received in the third year a course in neuropathology and formal clinical demonstrations in nervous diseases; in their fourth year they had section teaching and clinical and didactic lectures on both nervous and mental diseases. He believed that, if more time were set aside for special branches, internal medicine would not receive its due proportion. Special teaching, he believed, should be principally postgraduate.

Dr. Charles K. Mills, Philadelphia, feared that what had been said might be misinterpreted by some to mean that the occupant of the chair of the practice of medicine could teach neurology, and some other subjects, such as dermatology or pediatrics as well as the specialist, or better. Dr. Mills was strongly in favor of the teaching of the special branches comprised in general medicine by those best versed in those branches. He believed that special teaching should be proportioned to the time which the student had for everything.

Dr. Mills was inclined to believe that the American system was better than the English in having recognized specialists as professors and lecturers on neurology. He believed that they should also examine on neurology, that the examination should be controlled by the teachers of the subject; and that the student should be given a mark proportionate to the importance of the subject. He thought that good neurologic teaching could be given only by good neurologists.

Dr. Archibald Church, Chicago, said that the purpose at Northwestern University had not been to develop specialists; nor even to cultivate the research student especially. The school had for its object the production of practitioners of medicine, and this idea had been a controlling principle in the neurologic department. He said that in the second year a course in connection with the chair of physiology was given by a trained neuropathologist on the physiology of the nervous system. In this course not only was an understanding of the physiologic aspect of the nervous system sought, but attention was also focused on the modification of functional responses by pathologic conditions. Thus in conjunction, for instance, with the physiology of the reflex arc, the modification of the minor reflexes presented by diseases in various portions of the arc, or any conditions modifying responses in that arc, were brought to the attention of the student. He said that, in short, the symptomatology pertaining to the physiology of the nervous system was given to the second-year student. Neuropathology was taught as far as included in the general subject of pathology. The faculty hoped later to have a neuropathologist give those studying pathology a special course on the pathology of the nervous system in the second or third year.

In the third year a course was conducted by the assignment of a certain number of pages of text-book, portions of the text-book being selected for the purpose of training the student to a knowledge of symptomatology, including the methods of examination and the peculiar features of neurologic conditions. The purpose of this text-book course in the third year, Dr. Church said, was so to instruct the student that in his fourth year he might be in position to study intelligently the large amount of clinical material presented.

In the Northwestern University, as everywhere else, Dr. Church said, the internist desirous of doing everything, and the specialist desirous of teaching everything, had existed; but the tendency had been to subject the neurologic specialty to the field of general medicine; to attempt to teach as well as possible, special subjects, not with the purpose of making specialists and research students, but of so equipping the all-round professional man that when confronted with the ordinary or even with the rare forms of diseases of the nervous system, he might grasp the situation, make diagnoses, and give the best treatment provided by the medical profession. Dr. Church added that, on observing the work of the graduates of this school during the last eighteen years, it was seen that those who graduated ten or twelve years ago were not as well equipped as those who graduated five years ago; that cases of multiple neuritis were no longer brought to specialists with the presumptive diagnosis of tabes; that where formerly many rare forms of nervous disease were not recognized at all, it was no unusual thing now for recent graduates to bring cases of tumor well diagnosed, well located, well considered from every point of view; and that many of the rare forms of pathologic changes were equally well presented by them.

Dr. D. I. Wolfstein, Cincinnati, O., said that on account of the congenital aplasia of medical altruism in this country in connection with the acquired hypertrophy of political influence, it was doubtful if one would often have the opportunity of holding two chairs—one in internal medicine, and one in neurology. It was as much as any one could do under crude American methods to get one position. He said that many students after four years of the ordinary American curriculum, still looked on the pyramidal tract as some wandering pathway down the side of Cheops. There was, he thought, a considerable field for careful teaching of the student in college by the trained neurologist. Such instruction could not be properly given by the professor of internal medicine at all for his field was too broad, his time too limited, and his course too extended. Dr. Wolfstein doubted the wisdom of placing too much stress on a complete laboratory course in neuropathology. Neuropathology more than any other branch of pathology must be founded on thorough understanding of neuro-anatomy. Six weeks' instruction would be quite inadequate; three months might accomplish more, but he feared that all that the average student would get would be a hazy idea of the appearance of Weigert and Marchi specimens under the microscope. In order to draw any valuable deductions at all it was necessary to work intimately with the material for a long period of time and, as a rule, to cut complete serial sections. Much could be done, however, even in this short time and especially if the instructor demonstrated typical specimens.

Dr. Wolfstein believed that the great error in specialism to which Dr. Beevor had referred—one-sidedness—would be obviated only when men should take up the practice of neurology as a specialty after a thorough training in general medicine. To illustrate the errors in diagnosis made by practitioners without previous training, Dr. Wolfstein cited the case of a young lady seen by him who had been treated for neurasthenia for two or three years. Her temperature was 99.5, and Dr. Wolfstein, on careful examination, found that her neurasthenia was due to a widespread tuberculous involvement of both apices. Dr. Wolfstein thought that the tendency here as in England should be to specialize only after a broad general education and experience in the principles of medicine.

Dr. George Waterman, Boston, said that the case system of teaching had been adopted in the medical department of Harvard University, from the methods employed in the law school. The third-year students each provided themselves with a book containing reports of about one hundred and fifty cases, illustrating in various ways the different diseases of the nervous system with which they were expected to become familiar. In this book the organic and functional cases were mixed in such a manner that cases apparently more or less similar might have widely different causal pathologic bases. Students had their demonstrations and their lectures and discussions for the first two-thirds of the third year. The last third of the third year was given up to this system of case-teaching. Dr. Waterman explained that two students would be given one of these cases to study outside, having a week for preparation, and to arrive at their diagnosis. Then they were supposed to present the case to the class, first giving the focus of the lesion, then the nature of the lesion and its probable cause. They would then submit to questioning by the rest of the class. The subject would then be taken up for general presentation by the one conducting the course. This had been found a valuable method of making the students use their wits in making diagnoses themselves.

Dr. Waterman considered that the students still lacked that which could be acquired only by personal contact with the patient; and this was provided by the fourth year course of two months which was not intended to make specialists of the students, but simply to enable them to get at the root of the disease without having it presented to him by others.

In this course, which was taken by half the class in the fourth year, the men were made to take patients for half an hour, to take the history and make the diagnosis, and then to present the case to the class. He said that the students rarely specialized in neurology on graduation, but they were enabled to meet neurologic cases better than when prepared simply by didactic lectures and by the reading of cases.

THE GROWTH OF EDUCATIONAL REQUIREMENTS AND OPPORTUNITIES IN STOMATOLOGY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON STOMATOLOGY AT THE FIFTY-NINTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, 1908.

E. A. BOGUE, M.D., D.D.S.
NEW YORK.

It has seemed to me appropriate to draw the attention of the members of this body to the now rapidly changing conditions that affect our specialty. The physician and surgeon of long ago was supposed to be qualified to practice medicine and surgery in all its branches. The extent of the field presently caused certain ones, who had had their attention turned specially in certain directions, to become specialists.

About 1837 or 1838 the University of Maryland School of Medicine was petitioned to establish a dental department. The movers in this petition were themselves medical men who had turned their attention to affections in and around the mouth as a specialty. There were, however, so many others practicing this art, without any legal qualification, and engaged mostly in prosthetic work, that is, in supplying lost tissue, whether that loss consisted of parts of single teeth or of whole teeth or many teeth, that the Baltimore school returned a negative answer to the petitioners. These gentlemen being broader in their views than the authorities of the medical school, themselves founded a school in 1839 for the instruction of those wishing to practice dentistry, whether they were graduates in medicine or not.

From this small beginning in this country have grown the fifty-five dental colleges in the United States entitled to confer the doctor's degree without the full medical course. There are also two dental schools or departments in Canada, two or three in Italy, two in Switzerland, three or four in England having a limited connection with medical schools, and at least two in France acknowledged by the government as being of "public utility."

While a full medical course is not required of the dental practitioner in this country, Russia, Austria, Hungary, Roumania, Italy, and I know not how many other countries, all require a medical degree to be held by the practitioner of dentistry. A few countries—for example, Germany, Hungary, Austria, Spain—have provided a certain amount of dental teaching in their university courses, but the strictly dental and stomatologic teaching provided for the dental practitioner is quite as limited in amount as the medical teaching in the dental schools of America and England. When it comes to the treatment of serious oral disease, therefore, the stomatologists of Europe, as a class, look down on the dentist as lacking in professional training, while the dentist, engaged so largely in preventive work, looks on the medical man practicing dentistry as incompetent because he does not prevent the very diseases which the dentist has so assiduously qualified himself to treat; for the serious diseases, especially those requiring surgical treatment (unless they are congenital) are seldom if ever found in mouths where the teeth are in good condition. This, roughly stated, leaving out all unnecessary points, is the condition recognized by the stomatologists of Europe, who held a convocation in Paris last summer, from August 1 to August 5. This meeting was attended by about 250 men, all holding medical degrees, and a society was formed with a membership of about 400. Of this more later.

I may say right here that the intellectual qualifications of these gentlemen as a whole are, so far as I could judge, far in advance of any body of dentists of the same number that I have ever met. I make this admission now in view of certain criticisms which I feel bound to utter.

One incentive to this meeting of stomatologists was doubtless the refusal of the authorities, acting for the International Medical Congress to be held in Budapest in 1909, to recognize as members of the oral section any other persons than those holding medical degrees.

International medical congresses since the one held in Washington in September, 1887, which recognized dentists as practitioners of the healing art, have with one or two exceptions continued to recognize them, up to and including the meeting in Berlin, and to admit to the meetings of the oral section dentists in good standing holding degrees from reputable dental colleges.

The American Medical Association, thanks largely to the influence of Dr. Talbot, which has been continuously exerted for many years, maintains the same attitude still and admits to its section graduates of reputable dental schools.

The New York *Post-Graduate,* a journal of medicine and surgery, says in its issue for October, 1907:

> The first dentists of this country were nearly all graduates in medicine. The medical profession made a great mistake that it did not warmly welcome this new specialty taken up by men in its own ranks. It is our fault that all dentists are not first graduates in medicine, and many of them are. This error will finally be fully corrected. American dentists have made themselves famous throughout the world by their practical and scientific attainments. They were, in the beginning, members of our craft and would have remained so but for our failure to give them a warm welcome. Specialists in medicine were then under the ban.

This kindly prophecy presupposes that an ever-increasing number of educated men will adopt dentistry as a calling, and that the logical outcome will be that a larger number of dentists will take also the medical degree in order to fit themselves more fully for their life work, or else that each educational institution will make such modifications in its curriculum as to permit it to confer the medical degree, or its equivalent, on all medical specialists.

The establishment of independent dental schools was by no means an unmixed evil, for it has resulted in giving more or less training to a vast army of ingenious men, who have improved on their teachings until they have truly "made themselves famous throughout the world" for their skill, notwithstanding the limited scope of the teaching they had received and the limited field that they occupied. This led to concentration, and concentration has brought results, although the practitioners were not medical graduates.

It is true that many of the rulers and people high in political and social position in European countries have very generally employed American dentists when they were procurable, and on that account, I have been informed, police protection has been granted to a number of American dentists practicing abroad who had not the necessary legal qualifications for them to practice in the countries where their services were desired.

This condition of things would naturally cause the native dental practitioners, some of whom have been members of the government or of legislative bodies, to become very impatient. The result has been the passage of protective laws, ostensibly designed to protect the people from unskilled practitioners, but really operating to keep out foreign graduates of dental colleges.

This legal condition applies equally to England and France, Italy, Switzerland, Austria, Roumania, and various other European countries, in all of which the foreign dentist is disqualified unless he goes through the same preparation in the country where he wishes to practice as the native of that country is obliged to do before he can engage in practice. Those countries in which the laws requiring the dental practitioner to be a graduate in medicine are the most stringent are those in which the standard of operative dentistry is lowest. There are, of course, a few notable exceptions in every country.

What I have just said is not in disparagement of the very highest qualification possible for the practitioner of any branch of the healing art. It is a bare statement of facts with which we have to deal practically.

As I have previously mentioned, there was formed in Paris last summer an International Society of Stomatologists with a membership of about 400, to the presidency of which Prof. Joseph von Arkövy of Budapest University was called. The object of this society is to draw into closer relations the skilled practitioner of dentistry and the stomatologist, who is recognized simply as a medical specialist, like the rhinologist, the oculist or the gynecologist. Needless to say, it would please the stomatologists if all the first-class dentists became stomatologists, for the stomatologists can not all become first-class dentists, and they decline to be dentists on any other terms.

In 1903 the British Medical Association formed a dental section, thereby acknowledging the importance of dental and oral surgery and giving it its proper position in the medical world. Just at that time there was a movement made in England to separate dental surgery from the medical profession and place it on its own footing, as though it were possible to cut out one branch of the healing art and place it by itself. As if to emphasize the action of the British Medical Association, the new Royal Society of Medicine, formed in England and established in 1907, embracing all departments of medicine, included the entire Odontological Society of Great Britain among its members, thereby accepting quite a number of men who were not full graduates in medicine.

Coming now to our own country, we see that the result of the establishment of dental departments by a number of universities, and the introduction by them of dental teachings, has been to raise the standard of qualifications in every instance, so that in university towns where dentistry is taught the dental graduate of these universities takes rank at once with their other graduates in the estimation of the general public. All this indicates healthy growth and is but a repetition of the process by which the early barbers became surgeons and surgery took its place as the right arm of healing.

Our program shows what this Section is doing for advance, and I think our acknowledgments and sincere thanks are due to the members who have brought us these contributions in our special branch. We may well be proud of the progress indicated by these papers.

Dentistry has been a process of repair and has remained so up to now. It has the reputation of having made great strides; so it has, but principally along mechanical lines. Dr. Miller demonstrated the cause of decay. Dr. Black, by careful analytical research, demonstrated the reason for recurrent decay, and that led to what is now known as "extension for prevention." Dr. Sim Wallace and Dr. Harry Campbell of England have both gone further back, first in causation and then in preventive measures, and not only have announced their conviction that proper feeding would most effectually prevent decay of the teeth, but have put this theory into practice within the last few years by placing a considerable number of children on a diet calculated to promote the proper development of teeth, the proper growth of the jaws, and consequently the proper alignment of the two rows of permanent teeth in the jaws. This condition of things, as is well known to those who have spent any time in the study of the osteology of the head, face and jaws, leads to the formation of rows of teeth that are essentially self-cleansing in the presence of hard and fibrous food, and, therefore, are nearly or quite immune to decay.

The tendency of all research in this direction is to show that the luxurious mode of life of the more civilized countries, and especially of those members thereof who are able to select the finest food, requiring the least mastication and the least effort on the part of the partakers before it is swallowed, is not what is best for the health, either of the dental organs or the individual possessing them.

The effects on the face, nose and jaws of withdrawing the influence of hard and fibrous foodstuffs, which are the natural stimuli to the proper development and growth of these parts, are visible in the narrow jaws and irregular dental arches that so generally prevail. This leads to a general diminution of physical strength, resulting in a diminished resistance to infantile disorders, and almost always resulting in an incompleted adult.

In closing, let me leave this thought: If we "extend" our investigations and practice to "prevent" dental decay we shall most effectually practice "extension for prevention."

63 West Forty-eighth Street.

DISCUSSION.

Dr. G. V. I. Brown, Milwaukee, said that he believed that the meeting at Budapest was entitled to the very best assistance and cooperation it could get from the men in this country who believed the medical degree an advantage in addition to the dental degree. Comparison between the older countries and this was, however, difficult and uncertain because the whole scheme of education there was entirely different from the American. Dr. Brown said that the foreign course of study covered many more years than Americans usually cared to give; the actual hours of study were largely optional with the students, who took examinations pretty much at their own convenience. They drifted into one line or another of special interest to them, and Dr. Brown had learned that it was usual for men to continue in laboratory work there for ten and twelve years without any special thought of taking up the active practice of medicine. In this country, the class rules, the requirements of attendance, the rigorous way students were kept under control, almost like schoolboys, made the whole proposition entirely different. Dr. Brown said that many of the more highly educated men were not good operators in the technical parts of operative work; but on the other hand, some of the best operators this country had ever seen had been medically educated dentists.

Dr. M. H. Fletcher, Cincinnati, said that he thought that the knowledge gained by the study of medicine enabled one to make a more exact diagnosis and to treat in a more comprehensive manner the disease of decay. To him caries was a disease. Dr. Fletcher did not find that he could put in permanent fillings immediately in all cases. He noted the condition of the tooth and of the mucous membrane, and made up his mind from the symptoms and signs present whether or not it was a suitable case in which to do the mechanical piece of work which the non-medical practitioner would call the best operation. Dr. Fletcher agreed with the chairman that there was a higher plane of treating the diseases of the mouth than that which comprehended only the purely mechanical features.

Dr. Thomas L. Gilmer, Chicago, said that to him dentistry was part of medicine. There were many diseases in the mouth other than those affecting the teeth, and the dentist who did not take cognizance of them was not serving his patients in the best possible manner. Dr. Gilmer doubted if it were possible radically and quickly to change the present method of teaching dentistry. Liberally endowed schools for the teaching of dentistry as a special department of medicine might accomplish the change much sooner, but there were no such institutions. He thought that honest schools connected with honest universities should be encouraged and they would in time grow into higher and better things. Dr. Gilmer said that he was decidedly of the opinion that it was not practicable, at least now, for a dentist to secure the medical degree first and afterward acquire his dental education. He believed that, after a man had first graduated in medicine, the specialty of stomatology was not sufficiently attractive to induce him to spend two years more to qualify himself for its pactice. It seemed to Dr. Gilmer that while not the ideal, about the only practicable method at this time was to induce the dentist to continue the study of medicine to graduation after having gained the D.D.S. degree.

Dr. Eugene S. Talbot, Chicago, said that there should be no separate dental schools; all should be departments of universities; there should be no dental graduates; all should be university men on an equal footing with graduates of other departments of universities. The graduate of dentistry should, like other specialists, be educated in all departments of science. Dr. Talbot said that only three or four of the so-called dental departments were in reality dental departments of universities, and that the student's first lesson in dishonesty consisted in learning to believe himself that which he was not. There could be no middle ground: the dental schools were either schools of mechanics, or educational institutions fit to be associated with other departments of a university. Dr. Talbot believed that the weaker schools should unite with the stronger to reduce the number. There should be only one institution for dental instruction in each of the large cities or states. Dr. Talbot thought that the dental profession should anticipate disease and take up the study of preventive medicine. The time, he said, was ripe twenty years ago; and if the teachers in the dental schools had been educated up to the times by the reading of collateral science, they would now have fully equipped physiologic and pathologic laboratories for the purpose of experimental research. More than twenty years ago Dr. Talbot demonstrated the law of economy of growth, or use and disuse of structures. He said that there was a possibility of the prevention of irregularities of the teeth and decay, and that the experiment was worth the trial. The only way satisfactory work could be accomplished was to take a community of people and have them undergo the same methods of treatment for three or more generations.

Dr. Bogue, New York, said that dentists stood in a curious position. The men called in France *médecins de la bouche* (physicans of the mouth), and in Germany *Zahnärtzte* (tooth-physicians), were men who had been graduated as physicians, and later taken up dentistry. The consequence was that they did not at first know anything about denistry. Those men and a few others added had formed themselves into the Society of Stomatologists and ostensibly wished to unite with dentists. Dr. Bogue said that this was admirable, but the question was, how dentists could be parties to that union. Dentists were not all doctors of medicine, and stomatologists would not accept them unless they were. Stomatologists were not all good dentists, and dentists would be sorry to form a union with them unless they were good dentists. Dr. Bogue thought that dentists should be medically educated, but believed it wise to remember also that especially in a new country there were many people with limited income or opportunities who got toothache and were glad to apply to any one for professional services. Dr. Bogue knew that the wife and son of a member of congress went to the blacksmith in their native village to get their teeth fixed. A little knowledge might be dangerous, but it was also helpful.

Dr. Bogue defined good operators as those men who were able, for the longest possible time and in the best possible condition, to preserve in comparative health the teeth treated by them. It was not a question of fillings, which question did not and should not come up. Dr. Bogue could not approve of the destruction of tooth material which is now being waged throughout Europe and elsewhere, filing and chiseling and extracting right and left. It was not necessary, but those men who had not been instructed how to do otherwise were going to do that as the next best thing. European stomatologists, Dr. Bogue said, had not as a class undergone dental instruction, and American dentists lacked a medical foundation. He had hoped to receive light on the question of how to harmonize the two conditions.

A CASE OF ALTERNATING PERSONALITY.

CHARACTERIZED CHIEFLY BY AMBULATORY AUTOMATISM AND AMNESIA WITH RESULTS OF HYPNOTIC EXPERIMENTS.*

EARL E. GAVER, M.D.
Lecturer in Neurology in Starling-Ohio Medical University, Assistant Physician Columbus State Hospital for the Insane.
COLUMBUS, OHIO.

All of the cases of alternating personality probably are of sufficient interest and value in the study of hysteria to merit report. This account presents a picture perhaps only slightly different from some already recorded. The patient is possessed with a neuropathic constitution and presents a group of the stigmata of hysteria including the dissociation of the personality. The experiments serve to indicate a close analogy between the hypnotic state and the hysterical lapses. On the theory that all cases of dissociated personality occur in hysterical patients, and in view of the above analogy, we may be easily led to believe that all the departures from the primary or normal personality are partly self-induced hypnotic states. The most prominent features in the case are the ambulatory automatism and amnesia, both common characteristics of these peculiar and interesting hystericals. The usual, and what seems to be the patient's normal, personality we have designated as the primary state and the epochs of changed personality or the new condition the secondary state. In the abstract the case is as follows:

Patient.—Male, aged 29, white; electrician, American, average height, weight 163, and fairly well nourished.

History.—This was negative up to 1898 when he contracted typhoid fever while in the Spanish-American war. Since that time had had periodical (annual) attacks of "tender spine," and hyperesthesia along the left side involving also the left upper and lower extremities. Patient stated the pain was so intense that it caused a partial paralysis and that each succeeding attack seemed to be worse. The above condition he regarded as the result of the typhoid fever inasmuch as these attacks came on him each year about the same time he had the fever. Electrical tests negative.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908

Examination.—Physical examination revealed normal conditions excepting in the nervous system. He complained at times of feeling nervous. Deep and superficial reflexes all heightened and very prompt. Pupils variable, mydriatic most of the time, equal and reacted promptly to light and accommodation. Tactile sense was blunted on the entire left side and more deeply so in certain areas. Right side was normal. Allochiria was well marked on the back. Partial analgesia on the left side only. The thermic sense was considerably modified on the left side. He complained of paresthesias such as tingling, formication, and itching over the upper part of the chest anteriorly and posteriorly, also over the shoulders. A peculiar tender area extended from the base of the occiput medial down to the fourth cervical spinous process and over the left transverse process of the second cervical vertebra just below and anterior to the tip of the mastoid process on the left side. Pressure over this zone gave him an intense frontal headache. There was a marked superficial tenderness at these points, and he also had a marked tenderness over the left midpoint between the anterior superior spine of the ilium and the spine of the pubes.

The sensory symptoms were all variable. From time to time various symptoms had been presented that could be placed on the list of hysterical stigmata. The most prominent of these was his extreme suggestibility. This condition had been present at nearly all times and when hypnotic tests were desirable it facilitated them greatly. Variable anesthesia and other sensory phenomena were to be found at certain times. Abulia was a prominent characteristic in his case. There was a pronounced craving for attention and the patient would always see to it that he was not missed in the regular visits of the physician. Hypochondria was fairly well marked.

Patient's Story.—"In the fall of 1901 I was collecting for the Lynchburg Street Railway Co. One evening I was coming back alone from the country where I had been collecting money for some arc lights and motor-power and was crossing the bridge near home when I was struck a fierce blow on the head from behind. I did not remember anything more for about four days when I came to myself sitting up in bed and the first thing I did was to make a move for my pocket that had my money in it. The money had not been taken from me, however, but I had lost my watch and my own pocketbook with a small amount of money in it. I was afterward told that one of the conductors on the street railway saw me lying on the bridge and thought I was drunk and carried me back home. The doctors said I was struck with a sand bag. I was bruised on the back of the head. My head was so sore I couldn't touch it, and for about a month I did not go out of the house. From that time all that winter I was conscious, at times, of not knowing what I was doing, just at intervals probably lasting from fifteen minutes to half an hour.

"In the spring of 1902, I purchased a suit of clothes on Thursday. On Sunday morning when I got up to dress I found two suits of clothes exactly alike, afterward finding out I had bought the second suit of clothes not knowing what I was doing. I took it back and told the clerk in the store and he said when I was in there he thought I acted kind of funny. He asked me what I wanted and I selected a suit just like the one I had purchased a day or two previous. I commenced to get bad after that, that is, of getting a day, maybe two days which would seem like perfect blanks, to me. My home people didn't know what to make of me, and I told them that at times I didn't know what I was doing. I believed that blow on the head did most of the harm.

"In May, 1902, there was an excursion down to Norfolk, and I told my parents I was going to take that trip and go by boat to Baltimore and go to Johns Hopkins and seek a physician, in the hope that he might do something for me. I did not receive much attention from the physicians I consulted in Baltimore. This discouraged me. I sent word home that I would return the following week by the same route I had taken to Baltimore. However, at this time I lost consciousness of myself and when I came to, found myself in London, England. I didn't know where in the world I was and was very much frightened. On inquiry I found that I was in London, I didn't know whether I was dreaming or what had happened. I wandered around London and afterward found I was in Whitechapel. I wandered over on Commercial Road which is the main thoroughfare leading to the docks. Here I found a lodging house where I stayed over night and wrote a letter home. They would never show me the letter and that was the only time they heard from me while I was away. How I got across the water to London is something I have never been able to tell. I tried to find out but I never could. I tried every ship that came from Boston, New York, Baltimore and Norfolk, giving them my name and description, but could gain no information.

"The last thing I remember in London was being down by the old Tower, and the next time and place I realized anything was about two weeks later in Capetown, South Africa, and how I got there I don't know. Here I was more frightened than ever. I didn't have any money and was so far away from home. I secured employment as timekeeper for a contractor and went up to Johannesburg, about 250 miles over in Central Africa. Most of the time here I did not realize, yet I must have carried out my work daily as there was no complaint. At the end of two months I had about $225 which I thought was enough to take me home. I went to Capetown, got a vessel for London, sailed from London to Boston, and from there on home. I reached home in November, 1902, in such a condition that my mother couldn't recognize me. I got along very well without much loss of memory until the year 1905. At this time my mind was very clear, with the exception of an almost constant headache.

"In the meantime I had married and moved to Canton, Ohio, where I got along first rate until the above mentioned date, December, 1905. At this time, I again showed some loss of memory for certain periods. I was taken to a sanitarium in Columbus, remained there a short time, and was discharged as recovered. Secured employment in Columbus, operating an electric crane. I worked there one week, when I felt an attack coming on. I tried to wear it off; thought I could work it off. I left my home on Tuesday morning—this was in April—and the last thing I remember I was crossing Neil Avenue, which is about half a mile from the shop. The foreman of the shop told my wife that I went to work on the crane, operated it for about 20 minutes, came down and told him that my head was hurting so that I would have to go home. However, I came to myself in the afternoon of the same day at Newark, Ohio, not knowing where I was or how I got there. I telegraphed my people, and my brother immediately made arrangements for my commitment to this hospital."

First Attack at Hospital.—At about 8 p. m., May 22, 1906, the patient was standing on the veranda of the hospital, watching the fire department go by; soon after he turned and came into the parlor. In a few minutes he went to the interne's room and sat down on the bed, saying, "Oh dear, doctor, I am feeling so bad," and immediately fixed his eyes with a continuous stare and did not notice anything around him. His attention could not be gained by asking him questions, but after sitting thus for about ten minutes, the physician touched his wrist to feel his pulse, and he awakened with a start, looking up naturally and smiling. His pulse at the time was 102. The doctor resumed his reading, and the patient immediately returned to the stuporous condition. In about five minutes, with an offended manner, he got up and precipitously left the room, going to the west veranda. After a little while he was found sitting with his head in his hands. In an endeavor to open a conversation, all that could be obtained was, "Oh, my head hurts me so." At this time the nurse came out and told the patient it was time to retire, and in a moment he arose and walked to the parlor sofa throwing himself down. When again told it was bedtime, he got up, walked up and down the side hall, then entered his room and sat down on his chair and looked steadily out of the window. Later, the interne and nurse again enjoined him that he would better go to bed and began to take off some of his clothing in which he later assisted, but on getting him to bed, instead of lying down, he sat in a semi-recumbent position, leaning against the head of the bed, with his hands on his head. Just before getting into bed he said, "Where is Mattie?" (his wife's name) and in bed he said, "Oh, my head hurts so, I can't think." The interne revisited his room many times during the evening, always finding him with a fixed troubled look. He arose at 5 o'clock, walked into the west parlor, immediately sat down with his head in his hands, and with an expression of extreme dejection, entirely foreign to his usual smiling countenance. This position was not changed until the nurse asked him if he wanted to eat, which he seemed to understand perfectly, but would not speak, simply shaking his head. During the meal he walked into the reception room and leaned his chair back against the wall, sitting there with bowed head and strained expression till about 9 o'clock, then he suddenly awoke and was startled till he saw where he was. He then went to the nurse in an extremely nervous condition and asked for something to quiet his nerves. On being questioned concerning his spell, he said that he did not remember a thing after he was standing on the east veranda the evening before. He felt awfully tired and worn out as though, as he said, he "had done three weeks' work in one day," but his head did not ache so badly as it did the evening before.

Second Attack at Hospital.—In the evening of July 6, the physician asked how he was feeling, to which he replied, "Not very well, doctor, my head hurts me so." This was about 5:30 p. m. After taking a seat in one of the rooms, he was spoken to by one of the patients to whom he made no reply. He was then noticed to walk about the cottage till almost bedtime. He then went to his room, where he was found sitting on a chair peering steadily out of the window into the darkness. He had a very troubled, worried and sullen look on his face, and when the nurse touched him on the arm, acted as though he were angry. On being repeatedly told by the nurse and interne that it was bedtime, he did not move or take any notice of them, whereon he was undressed and put to bed without much resistance. He did not lie down, but sat up in a half reclining posture, which position he maintained till 10 p. m., when the nurses and interne were in the room, and at which time he suddenly awoke as if from a deep sleep. From the time we put him to bed till he came to himself, he had a heavy frown on his face, and kept slowly winking his eyes and gazing steadily at the foot of the bed. When he awoke, he said, "I am so tired," and then lay down on his pillow and was soon fast asleep. The next morning he was very weak and tired, and remembered nothing of the interval of time between 5:30 and 10 p. m. the evening before.

Third Attack at Hospital.—Patient was feeling in fine condition, July 22, until he had a little difficulty with one of the patients, which made him very nervous and out of sorts. He kept gradually feeling worse and his headache increased until on Monday, July 23, 1:15 p. m., the attack began. He was in his room staring out of the window, with a troubled look on his face. His pupils reacted sluggishly to light and his eyes were more or less fixed and staring. The facial expression was anxious and some times depressed, and he wore a frown continually. He did not seem to hear what was said to him and yet when told in a commanding voice to protrude his tongue, he did so, also stood up and walked down the hall and out the door; after this, he did not obey any commands. He would not answer any questions or give the least hint of a facial expression that would lead one to believe that he understood what was said to him. His leg and arm reflexes were exaggerated, especially the left side. He had a very noticeable tremor of his left leg. After the above observations were made, he was conducted out of the cottage to the grounds and allowed to go wherever he chose. He started direct for the gate leading to the street. He had his hands in his pockets, head down and eyes resting on the ground a few feet in front of him. He walked fairly rapidly, paying no attention to walks or driveway, but cutting straight across to the gate. He was followed closely, yet he took no notice of anybody, and did not seem to know anybody was around. On coming to the street, he turned and walked up it a short distance, and then on an intersecting street for one-half block. The physician called to him, but he would not stop. On catching up with him and taking him by the arm, without any particular resistance he was turned and started back. On reaching Broad Street, a street car was coming and he acted as though he wished to get on, and when the car stopped would have done so, had he not been prevented by his attendant. He wandered around on the street and then he was started back to the hospital, but he would not walk far till he would turn around and go towards the gate.

He would keep perfectly still when photographed; did not eat any supper, and sat for a while in his room where he came to himself at 6:10 p. m., feeling very much the worse for his experience. He asked for something to quiet his nerves. He ate a light lunch and went to bed, but did not rest well all night and felt very bad, weak and depressed all the next day, (Tuesday, July 24), and came in the office after supper, stating that he was trying to fight off a spell and asked to be allowed to stay up awhile till he overcame it, but at 9:10 p. m., he passed into his secondary state with a very deep frown on his face, just as though he was angry. On being advised to go to bed, he got up, and in an offended manner went to another part of the hospital, but would not talk, answer any questions, or pay any attention to anything we said to him. We kept telling him to go to bed, whereon he went into the parlor and sat down. The nurse took him out of the parlor and put him in his room, where he seated himself on his chair, and at 10:20 p. m. he was persuaded to go to bed. He partly undressed himself, being coaxed and commanded at times to do so. The interne was in to see him ten minutes later (10:30) and he had his head and shoulders propped up and steadily gazed at the foot of the bed. He remained in this condition all night, and in the morning dressed himself as usual, but did not eat any breakfast. His medicine was brought to him in his room, but he refused to take it. A few minutes later he came to himself, with a little start and jump. He felt very bad, but not nearly as much so as he did the day previous after the preceding attack.

Attack Occurring July 30, 1906.—In the afternoon of July 30, the patient repeatedly complained to the interne of feeling so weak and done up. Just after supper he asked for something to quiet his nerves. He said that he had a peculiar headache this afternoon, and felt as if everything in his body was trying to get into his head, and it felt so awfully sore. In the evening at 8 p. m., he came into the office and without saying a word, seated himself in a chair with his head resting on his right hand, his elbow on an arm of the chair, and his eyes fixed on the floor. When spoken to he did not look up or make any reply. He soon got up and walked out of the office, turned down the hall and went to his room. His face was deeply flushed, and he had an offended manner. He was observed in his room a few moments later (8:15 p. m.) seated on a chair with his head on the bed, and both hands holding the back of his head. He could not be roused or made to give any response whatever. A little later (8:30) the physician found him lying on the bed with his head and shoulders propped up high, eyes partly open and fixed. On commanding him to protrude his tongue, the scowl on his face grew deeper. He muttered that his head hurt him so badly. At 9 p. m. he had not changed his position and would not undress himself, but his apparent anger would increase when he was urged to do something. At 9:30 the interne and night watch went into his room and he was still in the same position, but a little more restless than usual, rubbing his hands over his head, sighing and exclaiming alternately from time to time, "Oh, dear," and "My head hurts so."

At 9:45 p. m. the physician found him sitting in one of the windows, looking steadily out and downward through the window. He refused to turn his head even when some force was used. He sat there for quite a while and then suddenly came into the interne's room and, sitting down on the bed, with his head in his hands, steadily gazed at the floor. He soon threw himself over on the bed, holding his head as if in intense agony, and exclaiming, "Oh dear." He groaned more or less while he was lying on the bed. Soon he muttered something, and on being asked several times what he said, he replied, "I want some smelling salts." On holding the cork from a bottle of aqua ammonia under his nose while he lay on the bed, he awakened with a sudden start, and looked at the physician and smiled, and said, "Oh, what a relief; please let me smell it again." A moment later he said that smell seemed to take an awful weight off his head. He said his head felt as clear as a crystal. He went to bed at 1:30 a. m. and said he was feeling fine, except that he was very weak.

First Hypnotic Experiment.—On the evening of September 20 the patient came into my office saying he felt quite miserable, suffering intensely with his head and feeling very nervous. Felt certain that he was about to pass into one of his states of secondary consciousness. I suggested that I hypnotize him, to which he agreed, stating that he had been hypnotized once by a professor. This was about 7 o'clock in the evening. I made the trial of hypnotism and succeeded in a very short time in having him under my control. I made several tests which assured me that he was hypnotized. At this time he was bearing an expression of discomfort and frowning. I suggested that he throw off that scornful expression and look pleasant and agreeable. He did this immediately. I also suggested that he was in a much better physical condition, and was not suffering any discomfort or pain, and judging from his expression, this seemed to be realized by the patient. I directed him to go to his room and take off his clothes and go to bed. This he did without any opposition whatever, carrying out every suggestion just as I gave it. After getting into bed, I suggested that he sleep soundly until 5 o'clock and then awaken and feel first rate and go to his breakfast. Our experiment, however, fell short somewhat in all this. He slept beautifully until nearly 2 o'clock, at which time he awakened and sat up in bed quite himself again. He soon began feeling bad, and at 4 o'clock got up and dressed. Later in the morning, at the regular getting-up time, 5 o'clock, he helped with the usual duties about the hospital, went to his breakfast, and about 6:30, as he was on his way down to the bathroom, lost all account of everything, and the secondary state was again on him. On visiting him about 7:30 I found him lying on the bed, looking very irritable and cross and displeased. At this time he would not talk with me, but clearly manifested that he didn't want anybody to bother him. I endeavored to engage him in conversation, but failed. I tried to get him up and have him move around, but failed in this. He would do nothing but lie on the bed, apparently angry about something. I didn't see him again until 11 o'clock, at which time he was sitting up in the chair in his room with his cap on, and looking in a staring manner out of the window. Seeing him with his cap on, I asked him if he wanted to go out, when this conversation took place:

"Do you want to go out?"

"I don't want to go with you."

"Do you know who I am?"

"Yes, I do." (Very cross.)

"Who is talking to you?"

"I know you all right."

"Well, who am I? What is my name?"

"I wouldn't be apt to forget you; it's Jim Fulton, and I know you well enough; you might as well go on and let me alone."

Seeing that he believed me to be some other individual, and that he was not friendly to this person, I didn't insist on talking with him much or doing much for him under this condition. He continued in this state, at times walking about in the cottage, trying to open the different doors, and seemingly wanting very much to get out and go somewhere. After failing to get out of the door, he would go to the window and look longingly. This lasted until 12:05 at noon, September 21, when he came to himself again, feeling very nervous and weak. Patient all this time stated that he didn't remember anything during the six hours of the lapse. When told of his irritable mood and mistaken notion concerning his physician, he regretted it very much and seemed to feel bad about it. On further investigation I found that Jim, the man referred to above, was a man of the patient's acquaintance, and was not very friendly to the patient, but repeatedly circulated stories reflecting on him. This accounts for the patient's irritable manner in my presence, while taking me to be this man.

Second Hypnotic Experiment.—Patient, with consent, was easily hypnotized with purpose of securing some history of some of his lapses. We know that in his primary state of consciousness he was entirely unable to recall anything that occurred during any period of secondary consciousness. Therefore, thinking that a state of hypnosis might aid me in adding the missing links of his life, I made the experiment with that end in view. As recorded above, we know that concerning his sojourn from Baltimore to London he knows nothing. Not a single event could be recalled. The same is true of his journey from London to Cape Town, Africa. Under the state of hypnosis he was enabled to recall nearly everything that occurred during that particular lapse or "spell." I learned that he traveled from Baltimore to New York by rail, going over the Pennsylvania Railroad. At New York he paid $55 for a ticket to London, making the trip in a fast vessel in six and one-half days. He traveled under the assumed name of Frederick Fields. He also revealed that after a few experiences in London he secured employment on a merchant vessel bound for Cape Town, Africa. On this vessel he labored in the kitchen and elsewhere. This much knowledge gained from him hypnotized satisfied me as to the success of the experiment, so I awakened him.

The ease with which the patient gave himself up to hypnotism and the very marked resemblance in expression, demeanor, etc., while in the hypnotic state to that while in the secondary conscious state was very striking. The chief difference, however, existed in the fact that while hypnotized he was amenable to suggestion and in the state of secondary consciousness he as a rule was not so. After coming out from the hypnotic state he felt the same tiredness and exhaustion he experienced after one of his periods in the state of secondary consciousness. Because of these facts I am led to suspect that the hypnotic state is closely analogous to the conditions of the dissociation of the personality.

The patient is still under my observation and has not had any disturbance in the field of consciousness since November, 1907, and the stigmata, excepting the abulia and suggestibility, have disappeared.

We regard the condition of the patient as improved only, and so long as the abulia and suggestibility remain we may look for a return of the dissociated personality. He is now employed as the hospital photographer and is getting along with ease and comfort, and this may be a factor in keeping him as well as he is at the present.

DISCUSSION.

DR. EDWARD P. ANGELL, Rochester N. Y., asked Dr. Gaver if he had looked up the data given by this patient in regard to his trips to London and elsewhere. Such statements were frequently the results of a dream-state represented by the mind as a fact. Dr. Angell added that fact and fiction were often alike to the patient.

DR. ALFRED GORDON, Philadelphia, said that he had reported, under the title of "Double Ego," the case of a young lady who told him that she had taken a trip to Europe and described, with such minute precision as to be almost convincing, the beautiful landscapes that she had observed in Switzerland and Italy. Yet Dr. Gordon doubted the story, and investigation proved it false. On another occasion, among many others, the patient told Dr. Gordon that she had been invited to play a certain rôle in a theater; that she had done so and met great success; that everybody had applauded her, and that many managers had invited her to appear in this rôle in different places. Inquiry proved this story also untrue; it was simply a case of subconscious state in a hysteric person with autosuggestions. Dr. Gordon explained that the patient had suffered from distinct attacks of hysteria simulating epilepsy; that she was accustomed to spend hours in reading, especially novels of the ten-cent order, containing wonderful descriptions and thrilling adventures, which were a factor in the suggestion which induced her condition.

Dr. W. T. Williamson, Portland, Ore., said that the likelihood of subjective error was sometimes in point, but it would not cover all such cases. Dr. Williamson cited a case in Council Bluffs. A young man left home to go down-town, and disappeared and was not heard of for several months. At length his parents got a cablegram from Australia from the young man, stating that he was there and wanted money to get home. The father and mother met the young man at Seattle, brought him to Portland and placed him in Dr. Williamson's care. Dr. Williamson said that though he kept the young man under observation for months, he never found anything that suggested fraud. At Seattle the patient's father made investigations which corroborated the young man's story. Dr. Williamson believed that these facts could not be explained by the hypothesis of dream-state, subconscious state, or fraud.

Dr. George A. Moleen, Denver, asked whether this subject had been afflicted at all with epileptic attacks. He remarked that he had seen a number of cases of postepileptic amnesia; one recently in which the patient's actions were automatic, during an attack of amnesia lasting for six hours. A number of cases in Denver had been under the observation of several neurologists, some of the attacks being of several months' duration; but no history of epilepsy was obtainable. Dr. Moleen said that he would like to know in all cases how many of the patients were afflicted with epilepsy.

Dr. G. P. Edwards, Nashville, believed that the diagnosis should be considered more carefully. He said that he had always looked on these patients as paranoiacs, or afflicted with periodical or circulatory insanity rather than with hysteria.

Dr. Gaver said that at the office of the ship company he had found that a man had travelled at the date mentioned by the patient, under the name of Fred Fields, the assumed name the patient had given while in the hypnotic state. Dr. Gaver could not give further corroboration except what was obtained through hypnotism. It seemed to him that if the patient's statements had not been true, he probably would not have been able to corroborate the story as he had told it while in the primary personality or normal state. The hypnotism, therefore, would have been the means of proving the fallacy of his story if it had been untrue. Dr. Gaver said that he had never seriously considered the case as one of epilepsy, not having observed any epileptic symptoms at any time. In substantiation of the diagnosis of hysteria, Dr. Gaver called attention to the fact that the case presented most of the major symptoms of hysteria, namely, marked suggestibility, abulia, breaking up of the field of consciousness, and very marked sensory disturbances, such as anesthesia and paresthesia. He did not regard the dual personality cases as epileptic or as the equivalent of epilepsy.

Serum Diagnosis of Syphilis.—Plaut, Heuck and Rossi, in the *Riv. di Patol. nerv.*, December 1907, xii, 12, conclude from their studies of the precipitation test of Fornet and his collaborators, (*Deutsche med. Wchnschr.*, 1907, No. 41) that this test can not be satisfactorily substituted for the deviation of complement test of Wassermann in the serum diagnosis of syphilis. They obtained the same reaction of precipitation by contact between the sera of syphilitics and paretics as well as between that of syphilitics and normal persons and also between two normal non-syphilitic sera. They do not deny the possibility of such a specific reaction under favorable conditions, but do not consider it reliable.

THE ATTITUDE OF NEUROLOGISTS TOWARD ELECTROTHERAPY.*

FRANK R. FRY, A.M., M.D.
Professor of Diseases of the Nervous System, Washington University.
ST. LOUIS.

The history of electrotherapy reaches back many years, a hundred or more. It includes a long list of names of those prominently connected therewith as investigators and writers, some of them very eminent. The investigations show at all periods much scientific effort, to say nothing of the voluminous records of enthusiasts that have no actual scientific value. The modern treatise on electrotherapy begins, much as its predecessors have, with a recital of the physical, physiologic and chemical effects of electric currents, but fails, as its predecessors also have, to establish any important relation between these effects and the therapeutic results claimed from the application of electricity to the body in various ways. The only probable exceptions to this statement are certain well-understood surgical results and some of the results of phototherapy, so-called. The body of the profession has not only been open to conviction, but it has anxiously, I may say, awaited convincing evidence that this agent would eventually yield certain specific or special therapeutic properties. So far it has not done so except in the limited field above indicated. This at least is the verdict of the great majority of those who are best prepared to render one.

The neurologist can not avoid the responsibility of an opinion in this matter, although he realizes that there is still a considerable contingent of the electropathically inclined who are anxious to contest his conclusions. A strenuous argument on therapeutic questions is rapidly becoming a thing of the past, and I have no desire to engage in one. My purpose is to state and to briefly explain what I believe to be the attitude of neurologists generally toward the use of electricity in those diseases which they are called on to treat: Neurologists more than any other class of practitioners are appealed to both by the laity and by other physicians for an expression of opinion in this matter because it is naturally supposed that they are the best prepared for one, and I think it must be conceded that they are. In the first place, the most numerous claims for electrotherapy have been made in the treatment of neuropathic diseases; second, there are few neurologists, especially among those who have practiced for twenty years or more, who have not used electricity a good deal; third, and most important, only those capable of making reliable diagnostic distinctions in neuropathic diseases are as a class capable of reliable opinions concerning the therapeutic measures to be addressed to these diseases.

The use of electricity in the treatment of neuropathic diseases does not in any instance rest on a scientific basis. It is as purely empirical, in this class of diseases at least, as any of the remedies employed in medicine. This means that the results attributed to it and the manner in which they are obtained are simply matters of opinion—always an unreliable kind of testimony, and perhaps never more so than in questions of therapeutics. For example, one observer relates remarkable effects from a battery from which no current issues: another, admitting the psychic origin of certain effects, prefers to produce them by the sensation of the passing current.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

To obtain certain results one insists on the galvanic, another the faradic and another the sinusoidal; another is confining himself to the static machine and getting more cures than he can account for; another is enthusiastic over electrophototherapy only; another has seen the most astonishing results from Arsonvalism.

Any one who has seriously and carefully used any kind of current in the treatment of disease for any length of time can truthfully testify that he has seen "good results," and even remarkable and astonishing things therapeutical. If he is a diagnostician he must soon discover that at least many of these results are psychic in their origin. He soon realizes, furthermore, that even if all the conspicuous results are not psychic he nor no one else has any means of proving the fact scientifically. In short, we know beyond question that many of the results are purely psychic, and we have no means of knowing that they are not all psychic. It will be readily seen that the whole argument reduces itself to a consideration of this fact.

Naturally, the neurologist with a growing diagnostic capability in neuropathic maladies has been first among practitioners to discern the psychic possibilities of certain remedies. He knows also what are the most convenient ones to use for this purpose and the proper places to apply them. He knows better than any one else, for example, where to use hypnotic suggestion and where electricity in order to test their greatest value, which means that he also knows where these remedies are weak or where harmful.

In the more serious and intelligent treatment of many neuropathic conditions we must rely on persuasion and education, i. e., persuasion in its technical sense and education in its broad sense. In doing this we strive for a deeper hold on our patient's ego, so to speak; a reliable footing in his confidence that can not be maintained by therapeutic clap-trap. Sometimes suggestive measures — electricity, for example — assist us in breaking into certain difficult psychic situations. For this purpose it is at times a convenience. But too often it is an inconvenience. The patient's cognizance of these things, i. e., of agents possessed of supposed special or unusual therapeutic power, is a hindrance, an inconvenience to the practitioner who is trying to reach an ultimate, a reliable therapeutic basis for a certain large class of patients. We can not teach these patients to rely on the simple hygienic measures in which they must eventually find security until we have entirely overcome their yearnings for therapeutic specialties. This is what we mean by the inconvenience of electricity, and not merely the inconvenience due to the time and patience consumed in handling electrical apparatus.

In view of the foregoing the futility of attempting to formulate rules for the use of electricity in this particular field is evident. Some will continue to use it extensively and find a satisfaction in doing so. One practitioner will write four times as many prescriptions as his next-door neighbor and intimate friend in professional life, but he can not convince this friend that it is commercially profitable or scientifically necessary to follow his example. Our therapeutic tastes and habits still vary with our temperaments and training, but we are learning to be very broad and charitable about questions of "practice" and scientifically more accurate. In short, we are all awakening to the great rôle that suggestion plays in the whole field of therapeutics and learning how to apply the gauges that are furnished by it.

Twenty years or more ago marked a period of great improvement in electrical apparatus. There began to appear perfected static machines, better and more convenient galvanic and faradic batteries, and appliances for controlling house currents, milliamperemeters and "normal" electrodes for measuring dosage, etc. With all this there was an increased interest and decided activity in the use of electricity, and many believed that an important renaissance in electrotherapy had begun. At that time neurologists quite generally began to equip themselves for a new trial, as it were, a scientific test, of electricity. Their verdict at the present time is founded on this kind of a trial.

In closing I wish to merely allude to the diagnostic use of electricity for the purpose of reminding my hearers, I hope unnecessarily, that neurologists as a class have not slighted any important known function of electricity in practice. The diagnostic value of it is appreciated only by neurologists, or those actually capable of diagnostic refinements in neuropathic diseases, and it is the only practical scientific use that has been made of it in medicine proper, and this, I repeat, is to the credit of neurologists alone, and they must also determine ultimately the therapeutic values of electricity in their particular line of practice.

DISCUSSION.

Dr. C. Eugene Riggs, St. Paul, said that commercialism had placed its stamp on the use of electricity; that manufacturers had flooded the country with various forms of apparatus, and that sometimes doctors had been unfortunate in their handling of this remedy, especially when they had placed it in the hands of incompetent nurses and ill-informed internes. As a consequence reliable data could not be expected regarding electrotherapy. Dr. Riggs said that nobody could question the value of cataphoresis in the relief of pain or of galvanism in the relief of neuralgias, or of the high-frequency current in the relief of pain and high arterial tension. Dr. Riggs said that electricity had a real tonic and sometimes a sedative influence.

Dr. William Benham Snow, New York, took an attitude opposite to that of Dr. Fry and said that Dr. Fry's premises were not based on scientific recognition of the physical or physiologic action of any of the electric currents. Dr. Fry had assumed that the effects of these currents were purely the result of suggestion. Dr. Snow said that if the current or the application of the current would remove pain, swelling, tenderness, and the lesion itself, in the case of a severe sprained ankle or wrist, it was something more than any suggestion that the personality of the physician could effect. Dr. Snow said that he knew from a long experience in the intelligent use of the static current that its great field was in its action on congested processes. He added that it must be understood and would be recognized in the future, if not to-day, that the treatment of nervous diseases was the treatment of inflammatory processes. Reflex neuroses, he said, unquestionably had their origin in, and were relieved by the relief of these inflammatory conditions. Dr. Snow said that he was effecting these results regularly in cases of neurasthenia, hysteria, neuritis and nervous diseases associated with every sort of inflammatory process; and these results were certain; there was no such things as failure in the treatment of localized uncomplicated peripheral neuritis or an inflamed joint, with the static current in the hands of an operator who was capable of applying it.

Dr. Charles K. Mills, Philadelphia, said that electricity in medicine had a field of usefulness, both in diagnosis and in therapeutics; but he thought that field a limited one, and believed that a definition of the uses and limitations of the agent would be most serviceable. Dr. Mills said that after many years of observation he was convinced that at times he was able to clinch the differential diagnosis of a peripheral from a central palsy, and perhaps to determine certain facts with regard to organs out of sight, by painful effects of the use of electric currents. Dr. Mills believed that electricity was largely a suggestive treatment, but not merely a method of treatment by suggestion. He believed with Dr. Mitchell that the skilful use of the faradic current in the treatment of patients suffering from neurasthenic conditions might prove useful by serving as a passive exercise, and in all probability by improving the condition of the blood. This covered much of its value even outside of neurasthenia. Dr. Mills said that neuritis, especially the chronic forms of it, could be treated with some advantage by a galvanic current of a moderate number of milliamperes, but he did not think this treatment beneficial in a wholesale way. Dr. Mills believed that pain not due to neuritis could also be relieved, not only by the currents of high-frequency, but by currents of the old-fashioned sort used skilfully. Some other beneficial results could be secured, as for instance in states of anemia and in some forms of indigestion. To make a sweeping assertion that the whole subject of these diseases of the nervous system and their treatment might be comprehended by regarding them as inflammatory with reflex results, was misleading. Dr. Mills believed that static electricity had some use. He stated that there was a good electrotherapeutic plant and an opportunity to test its value at the University of Pennsylvania. He said that it probably did some good in certain conditions of anemia and in a few other affections. Dr. Mills said that the value of electricity in medicine should be acknowledged but not exaggerated.

Dr. Wharton Sinkler, Philadelphia, thought that in many cases the effects of electricity were psychic, especially in cases of neurasthenia, hysteria, spinal tenderness, etc., but believed nevertheless that electricity had a distinct place in the treatment of various nervous diseases, more especially in the local palsies, facial paralyses, local neuritis and other conditions. He had recently seen a man with musculospinal palsy, the result of carrying a load of trees on his shoulder and arm. He had complete wrist-drop and palsy of the extensors of his fingers for eight weeks. After five days of faradism he was able to extend his wrist and fingers. That result was not psychic. Therefore, Dr. Sinkler believed that the proper use of certain forms of electricity was a remedy in many conditions.

Dr. Charles R. Ball, St. Paul, reported the case of a patient who had received a fall in a runaway and evidently had hemorrhage of the spinal cord in the cervical enlargement. He had something of the nature of the so-called Brown-Séquard symptom-complex paralysis of motion on one side and of sensation on the other. This man last winter had been brought into the hospital after having lain on his back three years, unable to feed himself and absolutely helpless. Yet in four to five months' time, with daily treatment by means of a simple faradic battery, the man had been put on his feet and was now able to walk several miles without sitting down, could feed himself and partially dress himself. Dr. Ball said that perhaps that result could just as well have been obtained by other means, but it seemed to him doubtful if any form of massage could so have selected and separated the muscles atrophied from disuse and from disease and have developed the muscles still capable of development as did electricity. It seemed to Dr. Ball that such results as that proved electricity an important factor in the medical armamentarium that should not be neglected. Another case cited by Dr. Ball was that of a man 75 years old, stupid and feeble-minded, with cortical degeneration, and blood pressure at 180. He had been a hack-driver but was entirely unable to follow his occupation, because of mental dulness. With treatment by autocondensation every other day, inside of ten days this man became bright, alert and natural; his blood pressure went down from 180 to 165. Dr. Ball believed that to be electrical nihilists would deprive the profession of the use of an important therapeutic agent, valuable where intelligently applied in many ailments.

Dr. Frank R. Fry, St. Louis, believed that the mere citation of individual cases would not have much weight without comparison with control experience and consideration of the different ways of looking at results by different persons. In the treatment of rest-cure cases, Dr. Fry said that he had formerly been accustomed to use the faradic battery, but he now found that he could get very good effects from brush massage. He had written his paper, not to deny the possibility of obtaining results from electricity, but to suggest the advantage of occasionally recasting current ideas on the subject.

THE SERUM TREATMENT OF EPIDEMIC CEREBROSPINAL MENINGITIS,

BASED ON A SERIES OF FORTY CONSECUTIVE CASES.[*]

CHARLES HUNTER DUNN, M.D.
Clinical Instructor in Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital; Assistant Physician and Pathologist at the Infants' Hospital.
BOSTON.

This report is based on a series of forty consecutive cases of epidemic cerebrospinal meningitis treated with Dr. Flexner's antimeningitis serum. All cases in which the *Diplococcus intracellularis* was found in the cerebrospinal fluid, without regard to the type of case or stage of disease, are included in the series. Sixteen cases occurred in the Children's Hospital in the service of Dr. Rotch, eight cases occurred in various other hospitals in cities and towns of Massachusetts, and sixteen cases occurred in private practice.

CONDITIONS OF ADMINISTRATION.

The antiserum was administered in all cases by injection into the cerebrospinal canal according to the technic recommended by Dr. Flexner and described in a previous publication.[1] As soon as a suspected case was reported to me, lumbar puncture was at once performed. If the cerebrospinal fluid obtained was cloudy, the antiserum was injected at once, without waiting for the bacteriologic examination of the cerebrospinal fluid, and if fluid was clear, no antiserum was given until subsequent examination revealed the presence of the *D. intracellularis.*

Thus in some cases of meningitis in which other organisms, pneumococcus or streptococcus, were subsequently found, the patients were given one injection of antiserum. In none of them did its use appear to do any harm. These cases are, of course, not included in the series, but are mentioned in order to bring forward the point that I believe the advantages to be gained by the earliest possible use of the antiserum in epidemic cerebrospinal meningitis are great enough to outweigh any possible disadvantage from its use in other forms, and that it should be used at once in all cases in which the patients have cloudy cerebrospinal fluid.

In those cases in which a rapid and marked improvement in the symptoms occurred after the first injection, accompanied by a permanent fall of temperature to the normal, no further injection was given. In those cases in which this did not occur, the injections were repeated daily until nervous and subjective symptoms were completely relieved and the temperature had reached the normal, or until four doses had been given. In resistant or relapsing cases further doses were given according to circumstances. The routine dose was 30 c.c.; in many instances larger doses were given, the maximum being 45 c.c. In some instances, when the amount of fluid obtained was small, and in all instances when too great an increase of intradural pressure was feared, smaller amounts were injected, the minimal being 10 c.c. This was the general routine; there were some exceptions.

---

[*] Read at the Annual Meeting of the American Pediatric Society, Delaware Water Gap, Pa., May 25-27, 1908. The discussion on this paper and on the paper of Dr. Churchill, which follows, will be found under Society Proceedings, this issue.

[1] Boston Med. and Surg. Jour., Feb. 19, 1908.

The serum has been used in forty-five cases of epidemic cerebrospinal meningitis, but cases still pending are not included in the series. Of the forty finished cases nine patients have died and thirty-one have recovered. This is a mortality of 22.5 per cent. and a rate of recovery of 77.5 per cent. Of the thirty-one cases in which the patients recovered, two were left with sequelæ, one being deaf and one both blind and deaf. The recovery was complete in twenty-nine cases, or in 72.5 per cent.

Mortality figures are never of conclusive value, on account of the variations in the mortality rate with various localities, seasons and epidemics. I believe, however, that this low mortality rate is of considerable significance as bearing on the value of the Flexner antiserum. I have collected a number of reports, from various epidemics and hospital records, from which the average mortality appears to be between 70 and 80 per cent. Although in certain epidemics it has been considerably lower than this, it has never fallen nearly so low as in this series of cases.

OBJECTIONS MET.

The significance of these figures as bearing on the value of the antiserum may be objected to on the following ground: That, as the mortality of this disease is known to present wide variations at different times, the present series of cases may represent a particularly mild type of disease prevalent this year in Boston and the surrounding cities and towns. In answer to this objection I would say that clinically the type of disease prevalent this year has not been milder than that which occurs every year sporadically in Boston and its vicinity. It must be remembered also that all types were included in the series, fulminating cases in which the patients were moribund when seen, chronic cases with the patients in the latest stage of exhaustion, and cases in which the patients died of an intercurrent disease while under treatment.

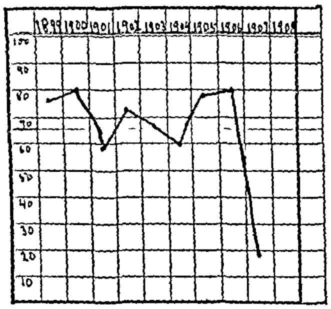

Figure 1.

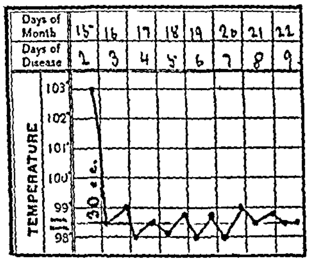

Figure 2.

Fig. 1.—Chart showing death rate from cerebrospinal meningitis at the Children's Hospital from 1899 to 1908.

Fig. 2.—Case 10. Showing temperature curve in aborted case. Early injection of antiserum followed by critical fall of temperature and immediate cessation of all symptoms.

The disease may for convenience be divided into the following types:

1. The well-known fulminating type, in which the progress of the disease was so rapid that the patients when seen were already in an extremely serious condition, with profound coma and weak heart.

2. Severe cases, in which the patients were unconscious, or in violent delirium, with poor general condition.

3. The common type, in which the patients were not unconscious, but very apathetic or in mild delirium, with fairly good general condition when seen.

4. The mild type, in which the patients were perfectly rational, with headache, rigidity, or retraction, and good general condition.

5. The chronic type, in which the patients were seen late in the course of the disease, unconscious, but without fever or active symptoms.

In the present series these types were distributed as follows:

Type.	Cases.	Deaths.
1. Fulminating	3	1
2. Severe	6	2
3. Common	19	1
4. Mild	6	0
5. Late chronic	6	5

BASIS OF COMPARISON.

I have not been able, for purposes of comparison, to collect enough cases treated in Boston and vicinity this year without the antiserum. It is possible, however, to compare the mortality at the Children's Hospital this year under the use of the antiserum with the mortality in other years under other methods of treatment, as sufficient cases have been treated in this hospital each year to afford a basis for such a comparison. While the number of cases treated each year varies, the average yearly number for the last ten years is twenty. This comparison also throws light on the comparative value of the treatment with the antiserum and of other methods.

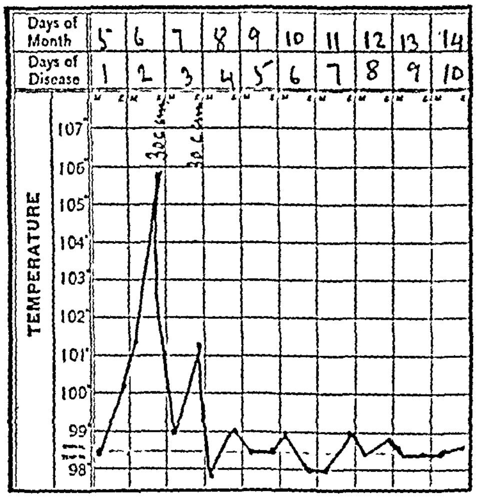

Figure 3.

Fig. 3.—Case 32. Aborted case, with slow onset on the first day, becoming suddenly fulminant on the second day. Injection of antiserum followed by crisis, and the immediate and permanent relief of symptoms.

Up to 1903 the treatment was largely symptomatic. In 1903, 1904 and 1905 lumbar puncture was largely employed as a therapeutic measure. Whenever the withdrawal of the cerebrospinal fluid appeared to be followed by improvement in the patient's condition, it was repeated at short intervals, particularly at those times when the condition showed any tendency to grow worse. It was concluded at that time that repeated lumbar puncture is of some slight value as a therapeutic measure. In 1906 the cases were treated by the frequent or daily administration subcutaneously of diphtheria antitoxin.

In 1907 a vaccine prepared from the *D. intracellularis* was used in connection with the estimation of the op-

TABLE OF RESULTS OF USE OF SERUM IN CEREBROSPINAL MENINGITIS.

No.	Age.	Dates of Injections.	Total Amount Given in c.c.	Maximum Single Dose in c.c.	Day of Disease.	Type of Case.	No.	Immediate Effect.	Duration of Fever.	Temperature Range.	Duration of Symptoms.	Result.

sonic index. Each year is regarded as beginning November 1 of the preceding calendar year, because we began to use the antiserum in November, 1907. I could not find any notable variation in the type of the disease from year to year. Figure 1 shows the figures.

It appears that the lowest mortality of any year before this was 58 per cent., and that it varied between 58 per cent. and 80 per cent., but that this year, under the use of the Flexner antiserum, the mortality has shown a remarkable drop to only 19 per cent. We may conclude that the other methods of treatment, vaccines, diphtheria antitoxin, and repeated lumbar puncture, are of little value in comparison with the antiserum.

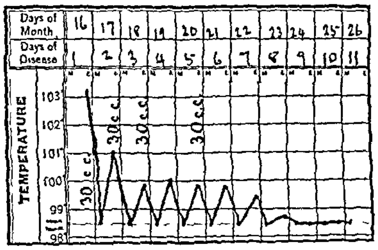

Fig 4.—Case 6. Early injection of antiserum followed by temporary fall of temperature to normal with marked relief of symptoms. Subsequent defervescence by lysis. This chart is typical of the commonest result of the early use of the serum in a severe case.

LIMITATIONS OF THE SERUM.

The nine fatal cases in the series throw a certain amount of light on the limitations of the value of the serum. Of these nine, five were cases seen late in the course of the disease, at a time when the patients were in the well-known chronic stage, unconscious, and without fever or active symptoms. In one of these the serum was not given until the patient was actually moribund. Of the other four cases, one was of the fulminating type, one a very severe case, and one patient died of an intercurrent bronchopneumonia, coming on after the temperature had come down to normal and all meningeal symptoms had subsided. The last case was one of average severity, in which the serum appeared to produce a slight improvement in the beginning, but which later appeared uninfluenced by the antiserum, advanced into the chronic stage, and a fatal result ensued after many weeks of illness.

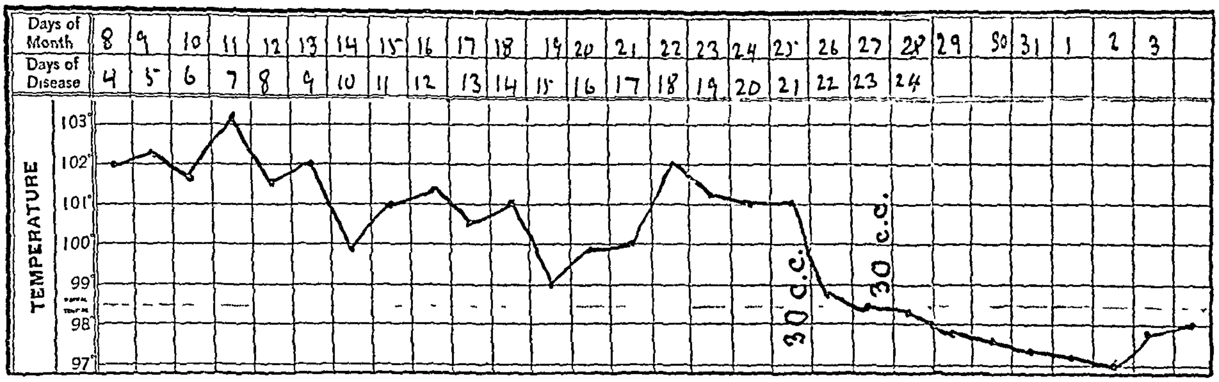

Fig 6.—Case 33. Late injection of antiserum followed by immediate crisis and very rapid convalescence.

My belief in the great value of the Flexner antimeningitis serum is based not chiefly on its apparent effect on the mortality of the disease, but on the very marked and striking effect which its use appears to produce in individual cases. It so modifies and changes the course of the disease as to present a very sharp contrast with the course usually seen in cerebrospinal meningitis treated by other methods.

Epidemic cerebrospinal meningitis, while showing wide variations in symptomatology and severity, presents certain characteristic features, to which we have become accustomed. In the fulminating and severe cases the patients either grow progressively worse and die in a comparatively early stage, or the disease gradually passes into a chronic stage in which the patient lies unconscious, with a varying fever for weeks or months. In time the fever disappears, but death usually occurs after a long period of illness. Even in the common and milder types, when recovery occurs, it is usually after a prolonged illness, often reaching many weeks. In the records of the last nine years at the Children's Hospital I could find no instance in which a proven case of cerebrospinal meningitis was aborted or terminated suddenly by crisis.

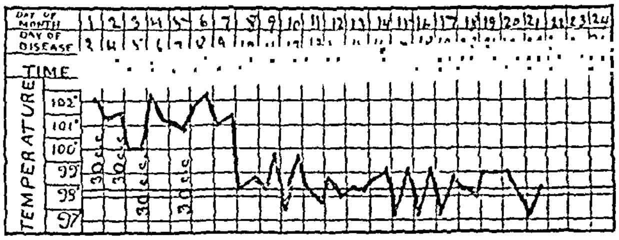

Fig 5.—Case 16. Early injection of antiserum followed by gradual improvement in symptoms, and crisis after five days.

EFFECTS OF THE SERUM.

The three principal effects of the use of the serum seem to be: First, to produce a fall of temperature: second, to produce a rapid improvement in the patient's general condition, accompanied by a more or less marked relief of certain symptoms, and, third, to cut short the course of the disease.

The most striking effect on the temperature is a permanent critical fall following the first dose of serum. This occurred in ten cases, the temperature falling at once to normal, or nearly normal, and showing no further tendency to rise. Other cases showed a similar critical fall of temperature, which was, however, not permanent, the temperature rising again and finally coming down by lysis. Such a temporary crisis occurred in four cases. Another effect was seen in a rapid permanent lysis, which was very striking in cases in which there had been a consistent high temperature up to the time when the first dose of serum was given. This occurred in nine cases. A similar lysis, but not permanent, the temperature going up again, occurred in two cases. A temporary sharp fall of temperature, not to the normal and not permanent, occurred in four cases; in these the temperature rose again, to come down by lysis later in the course of the disease. There was no immediate effect on the temperature noted in five cases. In the remaining six cases the patients had a normal temperature when the serum was given. See illustrative charts (Figs. 2 to 9).

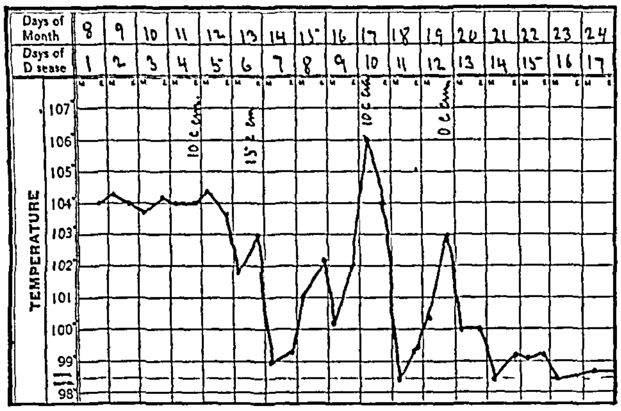

Fig 7.—Case 20. Tendency to relapse, controlled by small doses of antiserum.

ITS EFFECT ON SYMPTOMS.

The effect on the symptoms and general condition is the most striking phenomenon observed with the use of the serum. In some cases there occurred a permanent return to consciousness, a disappearance of mental dulness, a disappearance of delirium, and a disappearance of headache, hyperesthesia, tenderness of the neck or vomiting. These symptoms were often relieved completely within twenty-four hours after the first injection, the patient changing in the most remarkable way from a serious condition of coma to a favorable condition of normal mental activity.

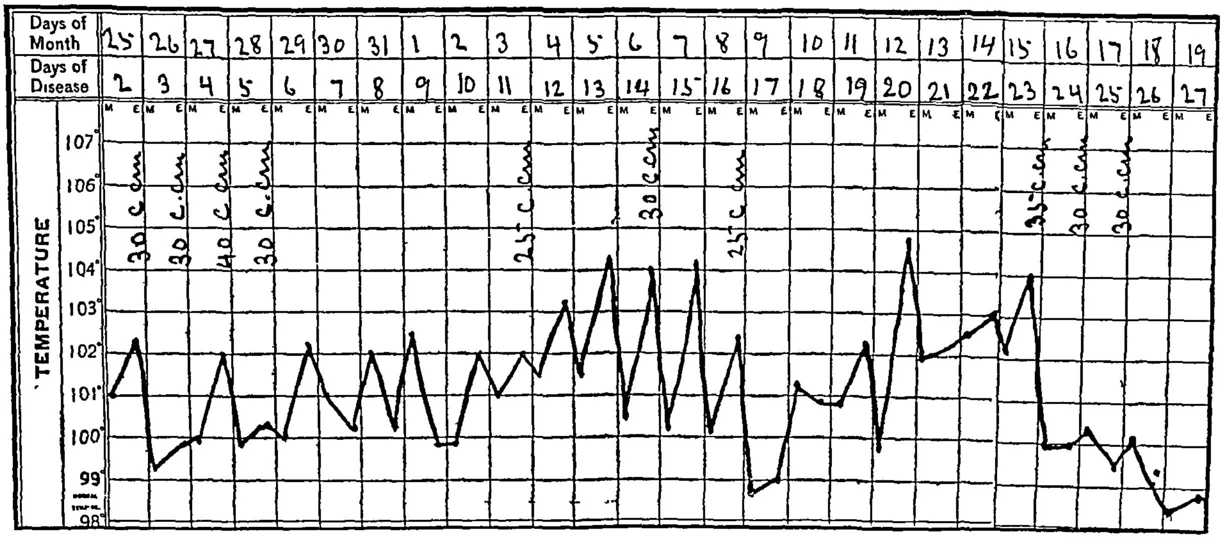

Fig 8.—Case 28 Resistant case, in spite of early use of antiserum. Early improvement in symptoms, but persistent fever.

At other times the improvement in this set of symptoms occurred more slowly, and at still other times, particularly in the late chronic cases, no such effect was noted. The rigidity of the neck and Kernig's sign were usually much more persistent, so that at times patients remained for some time normal in every way, even playing with the other children of the ward while these signs still persisted. The frequency of occurrence of this improvement in the symptoms and general condition is shown by the following table:

Improvement	Cases
Immediate marked ..	18
Immediate slight	6
Immediate temporary	4
Slower	7
None (all late chronic) ..	5

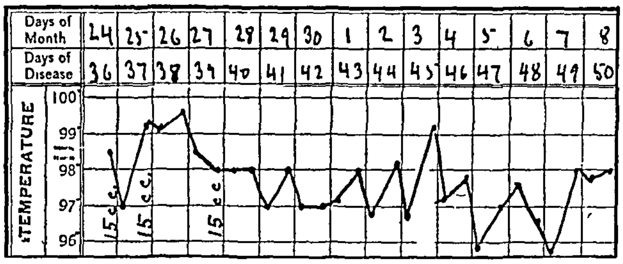

Fig 9.—Case 39 Late case in chronic stage, with subnormal temperature after five weeks' illness No effect from antiserum, and death from exhaustion

As to the cutting short of the disease, the average length of time which patients remained under treatment was but a small fraction of the time which patients who recovered remained under treatment at the hospital in previous years. The duration of symptoms after the first dose of serum, including the rigid neck and Kernig's sign, which were the last to disappear, is shown as follows:

DURATION OF SYMPTOMS

Weeks	Cases
1, or under	20
2	7
2 to 3	2
Over 3	2

ITS EFFECT ON THE CEREBROSPINAL FLUID.

Another notable effect of the serum is seen in the successive examinations of the cerebrospinal fluid during the period of its use. This effect is most striking in early cases, in which the cerebrospinal fluid contains large numbers of diplococci. In such a case a great many intracellular diplococci are observed in the fluid withdrawn by the first lumbar puncture. Twenty-four hours after the first injection the fluid presents a strikingly different picture. The whole number of organisms seen is much smaller, but the chief change is that the majority are intracellular, only rare extracellular forms being seen. The third lumbar puncture shows still fewer diplococci, and those only intracellular. In the fourth fluid, after three doses, there are frequently no diplococci to be found, or, at most, very rare intracellular forms.

Relapses sometimes occur under the use of the serum (Fig. 7). In a relapse, after a period of improvement, the symptoms begin to recur and the temperature to rise. This happened in seven cases. In two of these cases the serum was given in small single doses and was not repeated daily, although symptoms were not completely relieved, the treatment being repeated only in single doses when the relapses became plainly manifest. Each relapse responded to one dose of serum, but I believe the course of the disease would have been shortened if the treatment had been pushed at the outset, or if several successive doses had been given at the first relapse. In one case the treatment at the outset was interrupted by inability to obtain cerebrospinal fluid. Later, when the relapse occurred, it yielded promptly and permanently to three successive daily injections. In the remaining four cases the relapse occurred in spite of proper treatment at the outset. In two of these, treatment of the relapse by single doses of serum gave only temporary improvement, but both cases yielded permanently when four successive full doses were given.

THE LACK OF SEQUELÆ.

The completeness of recovery is another noteworthy point in this series. There were sequelæ in two cases only, one child being deaf and one blind and deaf. The results of the use of the serum appeared to depend chiefly on how early it was first used. The earlier it was employed the more marked were its effects. In 5 cases the disease was suddenly aborted after one dose of serum—that is, there was an immediate fall of temperature to normal and all symptoms were at once completely and permanently relieved. In 4 of these cases the serum was given in the first forty-eight hours. The fifth case was an exception, the disease having run a steady unchanged course for twenty-one days, with constant fever and symptoms. A crisis took place and there was complete relief of symptoms after one dose of serum. In 17 cases there was very rapid and permanent improvement, with a short convalescence. In 12 of these cases the serum was given in the first week, in 3 in the second week, in 1 in the third week, and in 1 case the patient was in the chronic stage, having been ill fifty days; in this case the temperature was normal when the serum was given, but the child was vomiting and in very poor condition. The organisms were still fairly numerous in the cerebrospinal fluid. Vomiting ceased and very rapid improvement occurred after one dose of serum. In 9 cases improvement was slower, with or without relapses. In 7 of these cases the serum was given in the first week, and in 1 in the second week. In 8 cases the serum had no marked effect; of these, 3 were in the first week, the other 5 being late chronic cases.

The relation between the mortality and the stage of the disease is shown by the following table:

Serum given in first week, 8 per cent.
Serum given in second week, 0 per cent.
Serum given after second week, 77 per cent.

We may conclude that the prospects of aborting or rapidly cutting short epidemic cerebrospinal meningitis are better the earlier in the disease the serum is given, and that the antiserum usually has no effect in the late chronic stage. There were cases which proved exceptions to this rule, as in three cases in which the serum was used comparatively early the patients died. On the other hand, one patient in the late chronic stage began to improve immediately after one dose of serum and made a rapid convalescence. This would show that there is always some hope of a good result so long as diplococci are present. I believe the serum in most cases causes a cessation of the active process and that the resulting course of the disease depends mainly on the extent of tissue damage which has already been done.

AMOUNT OF SERUM TO BE GIVEN.

As to the amount of serum which should be given, I was at first afraid to inject amounts larger than the quantity of cerebrospinal fluid withdrawn. After several patients, to whom small doses had been given, had shown a less favorable course, more prolonged illness and a tendency to relapse, I began to use larger doses. A few patients showed signs of collapse immediately after an injection, but in no case were these signs of long duration, nor did they end in death. I believe that 30 c.c. can be given usually with perfect safety, even when smaller amounts of fluid are withdrawn. I have given, without any bad results, as much as this when no fluid was withdrawn. One can judge to a certain extent how far it is safe to go by the feeling of resistance to the injection of the serum. In cases in which larger amounts of fluid are withdrawn I believe 45 c.c. should be given at a dose.

The daily injection of the serum in most cases seemed to be effective. After four doses have been given, if, after one or two days the case proves resistant, or at any time if there is a tendency to relapse, this treatment should be repeated. It is a question whether in some severe cases the serum should not be administered oftener than once in twenty-four hours. In two very severe cases death occurred in spite of the early use of the serum. In both of these cases a notable improvement was shown after the first dose and continued up to within a few hours of the time I arrived to give the second injection. Then both patients began to grow rapidly worse, so that when the second injection was given the condition of each was practically hopeless. I think it is possible these patients might have been saved by more frequent use of the serum, and I believe fulminating cases should be very closely watched and provision made for giving a second dose at any time.

CONCLUSIONS.

I conclude from this series of cases that:

1. The use of the Flexner antiserum is of great value in epidemic cerebrospinal meningitis. I believe its value to be comparable to that of diphtheria antitoxin in diphtheria.
2. The use of the serum at times aborts the disease, frequently rapidly relieves its symptoms, shortens its course, lessens the liability to sequelæ, and greatly reduces its mortality.

3. The serum should be used as early as possible in all cases, even of suspected epidemic meningitis.
4. It should be frequently repeated as long as there are symptoms or any tendency to relapse.
5. Late chronic cases are unfavorable for the use of the serum, but any case in which the diplococci are present has some hope of relief by its use.
6. Some cases are resistant.

220 Marlborough Street.

TREATMENT OF MENINGOCOCCIC MENINGITIS WITH THE FLEXNER SERUM.

REPORT OF CASES.*

FRANK SPOONER CHURCHILL, M.D.
Assistant Professor of Pediatrics, Rush Medical College.
CHICAGO.

I have had the opportunity of using the Flexner serum in 11 cases of meningococcic meningitis. The number is, of course, small, but I am reporting them now in order to call the attention of the profession anew to this method of treatment of epidemic meningitis. The serum is still on trial. Its efficacy is not yet proven. Enough has been accomplished by its use, however, to warrant, or rather to necessitate, a much more extended trial of it. It is desirable that it should be used in a large number of cases, records carefully kept, collected and analyzed. Dr. Flexner has kindly furnished me with the serum for general use in this community, requesting that records be kept of all cases, collected and forwarded to him.

In the 11 cases (all in Chicago) in which the serum was used, 7 of the patients have recovered, 4 have died. Of the 4 patients who died, only 2 of the cases were proved by bacteriologic examination to be of the meningococcic type, and, of these two, one was of the fulminating type, and in the other the patient entered the hospital in a moribund condition on the tenth day of the disease. Thus, in 7 of the 9 proved cases the patients have recovered.

It is not the purpose of this paper to describe at length the symptoms in the cases. All were clinically meningitis and, except in the two already mentioned, the meningococcus was found in the spinal fluid on lumbar puncture. I wish only to call attention to the effect of the serum on the disease as a whole, on the general condition of the patients, on the leucocyte count and on the spinal fluid as manifested by color, number of leucocytes and organisms.

The technic of giving the serum is simple. A lumbar puncture is done and, if possible, 30 c.c. of fluid is withdrawn. Then to the canula still in place is attached an ordinary antitoxin syringe, the serum poured from the bottle into the barrel of the syringe and allowed to run directly into the spinal canal. As a rule, the piston must be used to force at least the last part of the serum. The serum should be heated to body temperature before using. This may be done by standing it in warm water. Flexner recommends, for the present, a dose of 30 c.c., to be repeated every 24 or 48 hours, for 3 or 4 times if there be no improvement. It also seems safer to withdraw spinal fluid equal in amount to the serum to be injected, to avoid pressure symptoms. Some cases have been reported, however, in which no fluid whatever has been withdrawn and as high as 20 c.c. of the serum injected without bad results. If, for any reason, it is found impossible to inject into the spinal canal, the serum may be given subcutaneously, but good results are not expected by this method.

CASES

Case 1.—*Patient.*—R. S., school girl, aged 14, entered the Presbyterian Hospital March 11, 1908. Service of Dr. A. C. Cotton.

History.—Eleven days before admission she began to have severe headache, followed by vomiting. On attempting to walk, she would fall on her side. Unconscious since 9 a. m. of day of admission. Just before becoming unconscious she said she could not see.

Examination.—Well developed and well nourished girl, apparently moribund. Head retracted and rigid. Slightly cyanotic, breathing stertorous. Pupils dilated, reacting sluggishly to light. Deviation of eyes to left. Numerous medium and coarse râles everywhere throughout the chest. Respiration irregular. Heart regular, rapid, fair strength. Abdomen flat. *Tâche cérébrale.*

Treatment.—Lumbar puncture at 12 midnight, and about 30 c.c. of cloudy fluid withdrawn and 15 c.c. serum injected. Smears and cultures from the spinal fluid showed a gram-negative diplococcus, intracellular, corresponding morphologically and culturally to the meningococcus. Cultures from the nose showed the same organism. The child was practically moribund on admission. She sank steadily and died at 4 p. m. the next day, March 12. The temperature ranged from 101 to 103 F., the pulse and respiration were continuously rapid. The serum had no effect on her condition, except possibly on the leucocyte count. This was 34,000 at 11 p. m. on March 11, before the injection, and 24,000 at 11 a. m., the next day, 11 hours after injection. The drop may or may not have been due to the serum.

Case 2.—Baby R., girl, aged 2; service of Drs. Hughes and F. B. Earle, Chicago; entered St. Bernard's Hotel Dieu, March 4, 1908.

History.—Uncle died of meningitis years ago. Family history otherwise negative. Child was normal at birth, after an instrumental delivery. Never breast fed, brought up on artificial food; always delicate; had considerable digestive disturbance during the first few months of life. Early in January, 1908, had an attack of enterocolitis and "bronchitis," but improved after two weeks' treatment. For about one week before admission, had been drowsy and "lifeless," vomiting all food; had had apparent fever, restless sleep, retracted head and apparent general pain on being handled. No convulsions.

Examination.—Fairly well-nourished. Head square, retracted, produced pain on being moved. Chest negative except for rachitic rosary. Abdomen distended. Child lay with legs flexed stiffly and cried out when they were extended. Leucocyte count 30,000. Urine showed albumin, otherwise negative.

Treatment.—March 6. Lumbar puncture and about 30 c.c. of clear spinal fluid removed. Smears showed some polymorphonuclears. Baby seemed more comfortable and brighter after puncture.

March 9. Lumbar puncture and about 30 c.c. of spinal fluid withdrawn, clear and of same character as in former punctures. Flexner serum, 30 c.c., injected into the spinal canal. Baby seemed better after puncture and injection, for about 24 hours.

March 11. Child weaker; died at 12 midnight. Exact type was not determined, evidently.

Case 3.—*Patient.*—Moses S., aged 2, entered Michael Reese Hospital, Feb. 10, 1908. Service of Drs. Hess and Spitz.

History—Present illness began six weeks before admission, when mother noticed that the child did not look well, was not as bright as usual, cried much and was constipated. One week before admission retraction of the head began, increased steadily and when seen opisthotonos was quite marked.

Examination.—Marked emaciation, marked opisthotonos, purulent conjunctivitis. Numerous mucous râles everywhere over the chest. Abdomen negative. Kernig's sign present on both sides. Babinski reflex on left side only. Temperature, 96.7 F.; pulse, 148; respiration, 48.

---

* Read at the Annual Meeting of the American Pediatric Society, May 25-27, 1908.

Treatment.—Child remained in about this condition for two weeks with a low temperature, when a lumbar puncture was done and 20 c.c. of bloody fluid was withdrawn and 10 c.c. of serum injected. Seemed only a little better next day; second lumbar puncture and 15 c.c. of bloody fluid withdrawn, and 7.5 c.c. of serum injected. No particular change was noticed until two days later when child seemed weaker. Was then taken out of the hospital by the parents and died a few days later.

The examination of the spinal fluid in this case showed gram-positive diplococci and many polymorphonuclear leucocytes. Cultures were contaminated. The exact nature of the organism was never positively determined, but it evidently was not the meningococcus. The case can not be regarded as one of this type of meningitis and was, therefore, no test of the value of serum.

Case 4.—*Patient.*—Joe B., aged 16, school boy, entered Cook County Hospital, April 16, 1908, service of Dr. Kerr.

History.—Family history negative. Boy said that he had a tuberculous dactylitis a few months ago, for which the finger was amputated. Six days before admission he was running a great deal and got very hot. On the day following when he got up his neck was a trifle stiff and later he had some pain in the back. The next day his legs pained him somewhat. The stiffness of the neck had increased and the head had become retracted. No headache, no nausea, no vomiting.

Examination.—Well-nourished; lay with head somewhat retracted; face flushed. Eyes normal. Slight herpes about the angle of the mouth. The neck was rigid and movement painful. Kernig's sign present on both sides. No Babinski; movement of the lower limbs very painful.

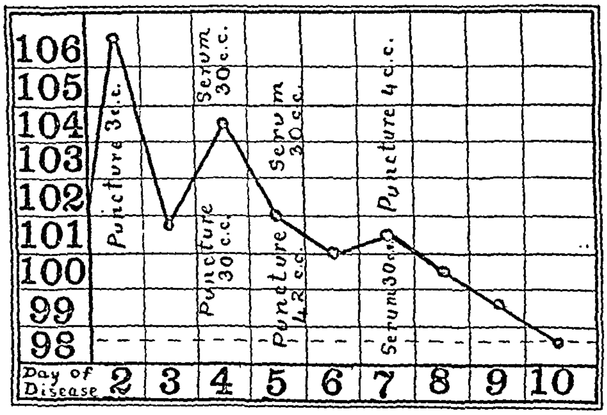

Fig. 1.—Chart illustrating temperature curve in Case 5, Frank J.

Treatment.—April 17. Lumbar, puncture and 30 c.c. of turbid fluid withdrawn, showing 2,880 leucocytes and 288 meningococci to the cu. mm. The diplococci were mostly extracellular, only 1.5 diplococci within the cell on the average. Blood: 13,600 leucocytes.

April 18: Better, less rigid. Lumbar puncture and 45 c.c. of turbid fluid withdrawn, containing fewer leucocytes and diplococci. Injection of 30 c.c. of serum into the spinal canal. Blood: 17,400 leucocytes. Restless and in pain for 6 or 8 hours after injection, then more quiet.

April 21: Much better, less rigid. Leucocytes, 15,800.

April 23: Improvement continued. Leucocytes, 20,200. Abdomen tender on right side.

April 28: Seemed perfectly well. Leucocytes, 10,200.

May 24: Went home, No sequelæ.

Case 5.—*Patient.*—Frank J., aged 14, printer, entered Cook County Hospital, April 12, 1908, service of Dr. E. F. Wells.

History.—Scarlet fever one year ago. Ear-trouble for years, with occasional discharge. No exposure to meningitis cases. Sore throat and earache five days before admission, latter was relieved by discharge from right ear. Continued to work until night preceding admission, when he went to bed with a severe headache, vomited (projectile), had a chill.

Examination.—Well nourished boy; complained at times of severe headache and pain in back of neck, and at times muttered deliriously. Neck was rigid, pain apparently increased on moving. Pupils equal and reacted to light. Tongue coated, breath foul. *Tâche cérébrale.* Both knee-joints exaggerated. Kernig's sign present on both sides. No Babinski.

Treatment.—Lumbar puncture done and 3 c.c. of very cloudy fluid removed with difficulty. Many large diplococci 6 to 12 in each field, and pus cells in smear; a few of the cocci intracellular. Cultures showed gram-negative diplococci.

April 13: *Urine showed a trace of albumin, otherwise* negative.

April 14: Restless and noisy. Lumbar puncture done and 30 c.c. of purulent fluid withdrawn and 30 c.c. serum injected. Blood: Leucocytes 22,400. Profuse perspiration 6 hours after injection.

April 15: Mentally clearer but rigidity the same. Convulsion at 6 a. m. Lumbar puncture and 42 c.c. of fluid withdrawn, less cloudy, containing about half as many leucocytes as on previous day and only one diplococcus to every 6 fields. Injection of 30 c.c. of serum. Blood: 17,000 leucocytes.

April 17: Better. Lumbar puncture and 4 c.c. fluid, less cloudy, withdrawn; and 30 c.c. of serum injected. Blood: 17,000 leucocytes.

April 19: Much better; entirely rational. Urticaria on face. Blood: 8,000 leucocytes.

May 9: Had progressed steadily. Urine cleared up. Went home well.

This was a very severe case, the boy being desperately sick when the first injection of serum was given and apparently having but a slight chance of recovery. The spinal fluid at the second lumbar puncture was thick with pus cells, and, on standing, looked like the urine from a severe case of pyelitis, with a thick layer of pus at the bottom of the glass. The response to the first injection of serum was striking, as evidenced by the clearer mentality, the drop in the temperature and leucocyte curves and the clearer spinal fluid the next day. He might have recovered without the third injection, but it seemed better not to take any chances.

Case 6.—*Patient.*—Margaret B., aged 7. from practice of Dr. E. A. Streich, Chicago.

History.—On March 28, 1908, *patient was taken suddenly* ill with a convulsion lasting about 5 minutes followed by complete unconsciousness for several hours. Later vomiting, restless *and crying out* in apparent pain.

Examination.—Patient unconscious, head retracted, neck and back rigid. Pupils dilated, did not react to light, nystagmus and strabismus present. Patellar and plantar reflexes, and ankle clonus all absent on both sides. Kernig's sign present on both sides.

Treatment.—Lumbar puncture and 10 c.c. of thick, bloody fluid withdrawn showing microscropically many red cells and a few polymorphonuclear leucocytes. No organisms found.

March 29: Patient still screamed on slight movement of head; opisthotonos marked, unconscious. Lumbar puncture and 15 c.c. of a thick, sero-purulent fluid withdrawn and 15 c.c. of Flexner serum injected. Microscopic examination of the spinal fluid showed many polymorphonuclear leucocytes, containing meningococci. Many diplococci extracellular. Cultures confirmed the smears.

March 30: Child partially conscious and complained of intense headache and severe pain in the abdomen; marked general hyperesthesia; very restless, but no longer vomiting.

March 31: Patient had not improved since previous day, still complained of headache and pain in abdomen; was crying. Rigidity persisted. Lumbar puncture, under slight chloroform anesthesia, and 15 c.c. of thin, watery, slightly turbid fluid withdrawn. It contained not nearly as many leucocytes as the previous specimen. Serum, 15 c.c. injected into spinal canal.

April 1: Child much brighter, recognized parents. No vomiting, some pain in head and abdomen. Slight opisthotonos, Kernig's sign less marked; slept comfortably a short time.

April 2: Conscious, resting quietly, opisthotonos nearly gone. Slight headache and pain in abdomen.

April 3: Cerebral symptoms had entirely disappeared, asked for something to eat.

April 4: Improvement continued. All rigidity gone; slept most of the time. From this time on the child made an uneventful recovery, except that on the thirteenth day of her illness she developed an urticaria, covering the entire body and causing intense itching. It disappeared within 48 hours. An acute parenchymatous nephritis was present at first, but had cleared up by the eighth day.

THE BLOOD DURING COURSE OF DISEASE IN MARGARET B. (CASE 6.)

March 29: Total leucocytes, 10,800; polymorphonuclears, 90.2 per cent.; lymphocytes, 9.3 per cent.; large mononuclears, 5.5 per cent.

March 30: Total leucocytes, 13,800; polymorphonuclears, 83 per cent.; lymphocytes, 15.4 per cent.; large mononuclears, 1.6 per cent.

March 31: Total leucocytes, 15,000; polymorphonuclears, 78.5 per cent.; lymphocytes, 19.8 per cent.; large mononuclears 1.7 per cent.

The total leucocyte count after this date ranged from 10,800 to 13,800.

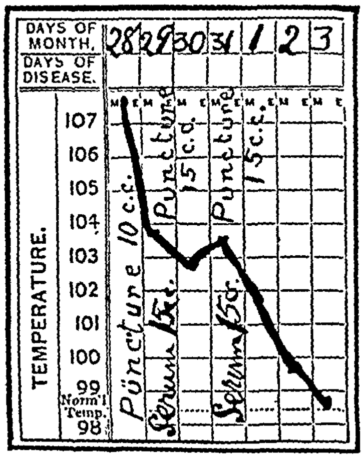

Fig. 2.—Temperature curve in Case 6, Margaret B.

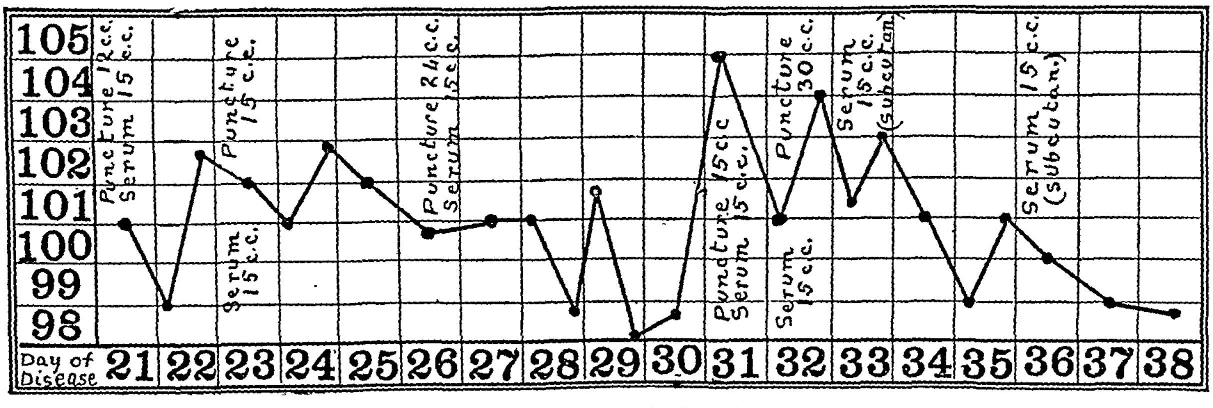

Fig. 3.—Temperature curve in Case 7, Herant M.

This was a very severe case and remarkably short in its duration. The rapid improvement after the injections of the serum made one believe that it must have been due to this method of treatment. The results are graphically shown in the temperature chart (Fig. 2).

CASE 7.—*Patient.*—Herant M., aged 9, entered Presbyterian Hospital March 23, 1908. Service Dr. A. C. Cotton.

History.—Patient was taken suddenly sick three weeks before admission with fever, nausea and vomiting, and rapidly became delirious. He could be aroused during the first three days but since then had been practically unconscious. Nausea and vomiting stopped after the third day.

Examination.—Child was semiconscious, head retracted, rigid, painful on motion. Pupils rather large, reacted to light. Cried much. Abdomen scaphoid and rigid. *Tâche cérébrale.* Extremities all rigid. Kernig's sign present on both sides. Patient cried out from time to time as if in pain. Seemed very sick.

Treatment.—Lumbar puncture done and 12 c.c. of turbid fluid withdrawn and 15 c.c. serum injected. Many meningococci and leucocytes in spinal fluid. Total leucocytes in blood, 15,000.

March 25: Lumbar puncture and 15 c.c. turbid fluid withdrawn, containing 2,400 leucocytes to the cu. mm. Injection of serum, 15 c.c. Blood: 12,000 leucocytes.

March 28: General condition the same. Puncture and 24 c.c. turbid fluid withdrawn containing 1,200 leucocytes to the cu. mm. Injection of serum, 15 c.c.

March 29: Brighter, less rigid.

April 2: Much worse in every way. Lumbar puncture and 15 c.c. fluid withdrawn, much more cloudy and containing 3,800 leucocytes to the cu. mm. Injection of serum, 15 c.c. Blood: 28,000 leucocytes; six hours after serum, 22,000.

April 3: No better. Blood: 21,000 leucocytes. Puncture and 30 c.c. bloody fluid withdrawn. Injection of serum 30 c.c.

April 4: Little more quiet. Leucocytes 20,000. Subcutaneous injection of 15 c.c. of serum.

April 7: Restless and noisy. Leucocytes, 12,000. Injected serum, 15 c.c., subcutaneously.

May 10: Steady improvement since last date, except for a mild attack of diphtheritic tonsillitis (ward epidemic). Went home well.

CASE 8.—*Patient.*—Wilbur L., aged 30, entered St. Luke's Hospital, April 15, 1908. Service of Drs. Nichols and Fuller.

History.—One sister died of spinal meningitis, not recently. On April 12 patient had a chill, followed by fever, vomited a great deal, had much headache and great pain in the neck. These symptoms continued for three days, when he became delirious and violent, continued thus for about twelve hours, when he became unconscious, in which condition he was brought into the hospital.

Examination.—White man, well built and muscular, in moderate coma. Head retracted; herpes on upper lip. Pupils small, equal and reacted to light. Nystagmus, eyes roll upward, photophobia. Tongue coated, breath foul. *Tâche cérébrale.* Kernig's sign present on both sides. Patellar reflexes decreased. Spine very rigid and flexion of it caused patient to cry out. Urine: Color normal, sp. gr. 1.025, much albumin, chlorids a trace only; sediment—a few red blood corpuscles, few leucocytes, few epithelial cells; few narrow, coarsely granular casts. Blood: 20,000 leucocytes, 99 per cent. of polymorphonuclears.

Treatment.—Lumbar puncture, 4 p. m. fluid turbid, straw colored and contained flocculi. Albumin 1 per cent. (Esbach). Sediment showed many leucocytes, 95 per cent. polymorphonuclears, 5 per cent. mononuclears. No micro-organisms in dried smears. At 11 p. m. puncture, 15 c.c. serum injected.

April 16: Following a bad night, patient seemed worse. Rigidity as on previous day. Blood: Red corpuscles, 4,700,000; leucocytes, 9,200; differential count, poly., 93 per cent.; small mono., 6 per cent.; large mono., 1 per cent. Cultures from blood showed no organisms after 48 hours' growth on bouillon. Lumbar puncture done at 5 p. m. and 30 c.c. cloudy fluid withdrawn and 30 c.c. serum injected. Patient desperately sick, had a bad day.

April 17: Another bad night; weaker. Grew steadily weaker and died at 3:15 p. m. Smears from the culture of April 16 showed the same number and proportion of leucocytes as on April 15. Cultures showed the meningococcus.

This was a desperate case, a fulminating one from the start, the patient dying on the fifth day of his illness. The serum apparently affected the leucocyte count, but had no effect on either his general condition or the character of the spinal fluid. Temperature went up steadily from 101 F. at admission to 106.5 at death.

Case 9.—*Patient.*—Raffaela, G., aged 30, house-wife; entered Cook County Hospital, April 11, 1908. Service of Dr. J. J. Herrick.

History.—Patient had been sick three weeks with severe headache, pain in back and legs. Six days before admission had a chill, two days later vomited and had another chill, more severe than the first, and has had slight chills every morning since.

Examination.—Patient lay in bed moaning at times. Seemed fully conscious of her surroundings, answered questions through an interpreter, but easily lapsed into a kind of stupor. Neck rigid and painful on moving. Face flushed. Pupils equal, contracted and reacting slightly to light. Tongue coated and dry. Abdomen retracted. *Tâche cérébrale.* Knee jerks brisk; Kernig's sign present on both sides; no Babinski. Blood: 19,000 leucocytes.

Treatment.—Lumbar puncture and 10 c.c. cloudy fluid obtained, many meningococci.

April 16: Restless and violent. Puncture and 30 c.c. turbid fluid withdrawn containing 4,250 leucocytes to the cu. mm., but only one diplococcus in several fields. Injection of serum, 30 c.c. Blood: 15,000 leucocytes.

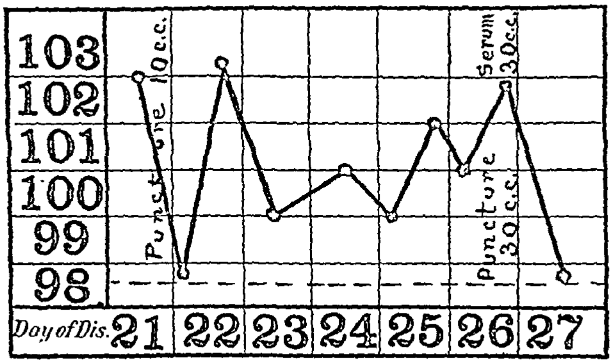

Fig. 4.—Temperature curve in Case 9, Raffaela G.

April 17: Leucocytes, 8,200.

April 22: Puncture unsuccessful.

May 9: Disease ran a protracted course, gradually clearing up. The single dose of serum may or may not have influenced the final result. The only immediate effect was the sharp drop in temperature to normal. It never went up again. A similar drop took place after the first puncture (without any serum), followed, however, by an immediate rise.

Case 10. *Patient.*—Charles T., aged 19, entered Presbyterian Hospital 7 p. m., May 8, 1908. Service of Dr. Billings.

History.—Patient was as well as usual on the morning of the day he was admitted and went to work. At 3 p. m., while at work, he was suddenly seized with a severe chill, followed by fever, pain in head and abdomen. He stopped work, laid down and slept for a few minutes and was then taken home and put to bed, talking incoherently. He vomited a small amount of greenish material. Temperature, 104 F.

Examination.—(7 p. m.) Well developed and well nourished young man. Head slightly retracted, not rigid. Eyes normal. Loud systolic *bruit* heard at the apex. Marked kyphosis in lower dorsal region. Extremities, flexed on abdomen. Kernig's sign absent on both sides. Babinski absent. Blood: (10 a. m.) 23,600 leucocytes; blood pressure, 98 mm. Hg. At 5 p. m., blood 28,000 leucocytes.

Treatment.—May 9: Had a restless night. Lumbar puncture done at 10:30 a. m. and about 30 c.c. of cloudy fluid evacuated under considerable pressure, containing 24,000 leucocytes to the cu. mm. Smears showed a gram-negative diplococcus 1 to every 10 cells, extra-cellular, resembling the meningococcus. Cultures confirmed this. Patient was not relieved by puncture. At 5 p. m., puncture done again and 15 c.c. of bloody fluid obtained and 25 c.c. of serum injected.

May 10: Restless for ten hours after puncture, then slept and awoke entirely rational, with normal temperature, but rigidity the same. Blood: 14,200 leucocytes.

May 11: Rigidity continued. Puncture done and 20 c.c. of fluid withdrawn containing 6,000 leucocytes and 212 diplococci to the cu. mm. Injected serum, 30 c.c. Blood: 10,800 leucocytes.

May 15: Been doing well. Restless, pulse irregular. No apparent cause for elevation of temperature.

May 18: Kernig's sign gone. Neck a little rigid.

May 25: Practically well, though still in hospital.

Case 11.—*Patient.*—Annie B., aged 11, entered Cook County Hospital May 11, 1908. Service of Dr. I. A. Abt.

History.—Patient was taken ill suddenly about 2 a. m., May 8, with pain in back of head and neck, which continued to increase in severity, with rising temperature till about 7 a. m., when she became semi-delirious. She continued in this condition until she was brought in to the hospital at noon, May 11.

Examination.—Child well developed and well nourished. Semi-conscious, head markedly retracted, body and limbs rigid. Face flushed, respiration rapid and irregular. Herpes on lips. Pupils unequal, both responded sluggishly to light. Tongue badly coated, breath foul. Semi-purulent discharge from nose. A few petechial-like spots on front and upper part of chest. Few râles over lower lobes of lungs posteriorly, both sides. Heart, rapid but irregular. Abdomen rigid, otherwise negative. Extremities all rigid; thighs flexed on abdomen. Kernig's sign present on both sides; reflexes absent. Child very sick.

May 11: (5 p. m.) Lumbar puncture done and 25 c.c. of turbid fluid withdrawn containing many leucocytes and a few extracellular diplococci. Injected 30 c.c. of serum. Blood: 18,000 leucocytes.

May 12: About the same at 4 p. m., lumbar puncture was done and 30 c.c. of turbid fluid withdrawn showing 80,000 leucocytes to the cu. mm. and 9,000 diplococci (3,000 extra- and 6,000 intra-cellular). Injected 30 c.c. of serum. More quiet after injection and rational by 8 p. m. Blood: 29,800 leucocytes.

May 13: Brighter mentally, but still rigid and pulse irregular. Puncture done and 30 c.c. fluid withdrawn less turbid showing 11,400 leucocytes and 855 diplococci (570 extra- and 285 intra-cellular).

May 14: Much brighter; playing with the other children, though the head was still retracted and she was generally rigid. Blood: 15,200 leucocytes.

May 16: Continued to improve. Leucocytes 17,800. Cause?

May 18: Seemed perfectly well; no rigidity; Kernig's sign gone. Leucocytes, 25,000. Cause?

May 24: Smear from vagina showed a diplococcus resembling the gonococcus, probably causing the leucocytosis (15,000 to-day). Still under observation.

Observations have been made, in these cases, on the general condition, on the temperature, on the number of leucocytes in the circulating blood, and on the spinal fluid.

GENERAL CONDITION.

As a rule, the patients were more comfortable after a puncture and injection, though in one or two of the cases this did not take place for several hours after the puncture. The immediate effect of this procedure seemed to stir up the patient. None of the punctures were done under an anesthetic, but I believe that there would be considerable saving of wear and tear in certain patients if they were given an anesthetic, for example, those not very toxic, but in a fairly conscious condition.

The first sign of permanent improvement noticed in at least 5 of the patients was a clearing up of the mental condition. They became perfectly rational after an injection (not always the first one), were more quiet, while the rigidities were still very marked. It was a curious sight to see the patient lying in bed with head strongly retracted, yet with no expression of pain; quiet, looking about and interested in the ward doings.

THE TEMPERATURE.

The temperature has shown a decided tendency to drop steadily from the beginning of treatment, at least in those cases running a short course. This is especially notable in Case 6. This was not so pronounced in the more protracted cases, for example in Case 7, the course of the patient's temperature was not steadily downward, yet even here we see a decided tendency to remit after individual injections. The more prolonged course, with a sharp exacerbation, was undoubtedly due to the fact that he did not come under treatment till late in the disease—the twenty-first day. Also he was the first patient in whom I used the serum and we were possibly somewhat timid in our dosage. I believe we should have given him the full doses from the start. The two subcutaneous injections, by the way, seemed to produce as quieting an effect as did the intradural ones.

THE LEUCOCYTE CURVE.

The effect of the serum on the total leucocyte count was striking and uniform. There was almost invariably a drop after the first injection, sometimes to a marked degree, e. g., in Case 6, from 19,000 to 13,000 within 24 hours after the first injection; Case 5, from 22,000 to 17,000; Case 10, from 23,000 to 14,000. In Case 11, a very severe one, the first injection failed to produce any effect on the general condition, and the disease apparently continued to advance, for we see in the first 24 hours a jump in the leucocyte count from 18,000 to 29,000. Then the second injection evidently began to produce its effect, as was seen by the brighter mental condition of the patient and a considerable drop in the leucocyte count, from 29,000 to 15,000.

I am unable to account for the continued leucocytosis in Case 4. It was not accompanied with a high temperature, nor lack of improvement in general condition. The patient had, however, considerable tenderness and some dulness in the right iliac region and it is possible he had some slight trouble with his appendix. Everything eventually cleared up. In Case 8 the drop from 20,000 to 9,000, with a steady advance of the disease to a fatal issue, was due presumably to lack of resisting power on the part of the patient and is comparable to the similar phenomenon observed in fatal cases of lobar pneumonia.

THE EFFECT ON THE SPINAL FLUID.

It being particularly desirable to have information as to the effect of the serum directly on the seat of the disease, special attempts have been made to study the spinal fluid. The color has been noted in all cases, the number of leucocytes and organisms present, in 6 cases. The fluid has, of course, been turbid at the first puncture, in one or two instances clearing up at the subsequent punctures, in others not.

The number of leucocytes to the cu. mm. has been counted as in the blood. They have ranged from 2,400 to 80,000 in the first puncture, and from 80 to 7,000 in a final puncture. The last puncture done generally showed a decided drop in the number of cells. The count in Case 7 is of special interest, showing a decided increase over that noted in the previous puncture, from 1,200 to 3,800, coincidently with an increase of all other symptoms and signs, temperature, total leucocytes, etc.

The leucocytes were, of course, largely of the polymorphonuclear variety. The proportion has been noted in only one case (Case 8), in which it showed 95 per cent. of polymorphonuclears and 5 per cent. of mononuclears.

The number of organisms to the cu. mm. in the spinal fluid has been estimated roughly by counting both leucocytes and diplococci in several fields, noting the proportion and then calculating the latter from the leucocyte count. Thus in Case 10 there were 24,000 leucocytes to the cu. mm. and about one diplococcus to every ten cells, making approximately 2,400 organisms to each cu. mm. They also decreased with the progress of the disease.

SIGNIFICANCE OF THE RESULTS.

The number of cases reported in this paper is, of course, small, and taken by themselves would be of no significance. Taken with the cases already reported by Flexner and his other investigators, the results of this treatment of meningococcic meningitis are most remarkable. As one watches the behavior of these patients after one, two or three injections of this serum, he is impressed with the astonishing change which comes over them, the clearing mentality, the unsuffering expression of countenance, the evident comfort, even with a still retracted head and rigid muscles, and he is filled with an optimism as to the ultimate result which perhaps is not yet justified.

Enough has already been done by the serum, however, to warrant its use on a wide scale, and it is not too strong a statement to make that, given a case suspected to be meningitis, it is our duty to do a lumbar puncture and, if we get a cloudy fluid, to inject the serum at once and repeat it if bacteriologic examination prove the case to be one of the meningococcic variety.

I wish to thank Dr. Flexner for the opportunity of using the serum, and also the various physicians who have allowed me to study the effects of the serum on their patients. My thanks, also, are due to all the internes at the various hospitals for their cordial and interested help in the laboratory investigations of cases. Their assistance has been much appreciated.

OBSERVATIONS ON THE THYROID AND THE PARATHYROIDS.*

HERMAN TUHOLSKE, M.D., LL.D.
ST. LOUIS.

With our forebears, anatomy was the handmaiden of surgery; pathology its judge or jury. Modern aggressive surgery, the veritable *sectio in vivo,* demands of the anatomist a closer study of the viscera and ever and anon puts new problems before the physiologist.

The enormous amount of anatomic, embryologic, physiologic, chemical and animal experimental work on the thyroids and the parathyroids, growing out of the recognition of definite groups of postoperative symptoms, has shed much light on, and aroused much interest in, the functions of these important structures. I may not venture, because of the necessarily limited time alloted to this paper, to give even a cursory epitome of modern research work, but may attempt to state the conclusions which, after a fairly complete review of the work done by hosts of experimenters and observers, and my own limited part therein, appear to me to logically present the present status of the subject.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

EXPERIMENTERS NOT UNANIMOUS.

It is but fair to state that some observers and experimenters of note are not in accord with the majority of workers and the conclusions currently accepted. Vincent and Jolly say that neither the thyroids nor the parathyroids are to be considered as organs essential to life. Rats and guinea-pigs do not seem to suffer from the extirpation of the parathyroids; monkeys show only transient symptoms; dogs, cats, foxes and prairie wolves frequently suffer and die. On the other hand, badgers (purely carnivorous animals) are not affected by the operation. When parathyroidectomy proves fatal it is probably due to severe injury done to the thyroid. The thyroid and the parathyroids are to be looked on as a single physiologic apparatus, the two kinds of tissue being intimately associated embryologically and working together physiologically. When the thyroid is removed the parathyroids appear capable of functionally replacing it to a certain extent and their histologic structure changes accordingly.

Blum says the thyroid is no secretory gland, but a detoxicating organ, which by the removal of toxic material from the circulation by intraglandular detoxication exercises a protective power on the central nervous system. The thyroid has especially the power of splitting off iodin. The iodin stored in the thyroid never leaves the boundaries of that organ. Blum can not subscribe to the prevalent view that the parathyroids play a separate and distinct rôle. He accepts the dictum of Kishi, who says morbus basedowii can not be the result of hypersecretion of the thyroid, since the thyroid normally produces no secretion. The assumption of thyroid insufficiency alone can justify the foregoing observation. Basedow's disease must be treated by a diet free from meat. Kishi claims that his therapeutic results are as good as those obtained by surgical measures and, being without danger, are to be preferred. According to his view, the operation which reduces the thyroid mass is to be abandoned.

VIEWS GENERALLY ACCEPTED.

The large majority of writers hold views opposed to the foregoing. The views entertained at present are that the thyroid and parathyroids differ embryologically, histologically, anatomically and functionally. The removal of all parathyroids in man and in many animals is followed by tetany and death; the removal of the thyroid by chronic nutritive disturbances which make up the picture of cachexia strumipriva, eventually ending in death. Erdheim's experiments on rats for the demonstration of the consequences of the destruction of the parathyroids led him to assert that not the loss of thyroid substance but the destruction of the parathyroids is followed by tetany, and he furthermore was able to prove that in three cases of strumectomy, followed by tetany, the parathyroids were wanting or had been destroyed. McCallum in his experiments on dogs found tetany to follow the removal of the parathyroids, and so did a host of noted observers. Death from complete parathyroidectomy may be deferred for a time by feeding with beef parathyroids, and acute tetany entirely prevented, as demonstrated by Halsted, McCallum, Beebe and Rogers. Feeding with thyroid extracts or iodin-containing albumins, iodothyrin and similar preparations will overcome many symptoms of cachexia strumipriva and prolong life. After the removal of the thyroid gland the parathyroids never change structurally, never get to be like, never resemble thyroid tissue and never assume its functions. The removal of both is followed by death, the chronic symptoms perhaps predominating.

ANATOMY AND PHYSIOLOGY OF THE PARATHYROIDS.

The knowledge of the anatomy of the parathyroids and their arterial supply has by the labors of Halsted, Evans, McCallum and others become quite exact. On a few points the observations differ slightly. First as to the number of parathyroids in man; four is the usual number; there may be fewer and occasionally one more. Verebely found four parathyroids in 108 out of 138 autopsies. Thompson and Harris in 250 routine autopsies in the St. Louis City Hospital found four parathyroids in 90 per cent. of the cases. They also found in their experimental work that the *symptoms resulting* from slow deprivation of functionating parathyroid tissue differ materially from those following extirpation of the glands. The slow deprivation of functioning parathyroids was produced by as complete devascularization as possible. The animal (in their cases the dog) dies eventually; but instead of the acute tetanic death which follows excision, with slow *destruction of the glandules*, the animal loses in weight and strength, disturbances of a trophic character ensue, and finally a comatose *condition ends the scene* without tetany.

These observations are not quite in accord with the presentation of the subject in the classical article on "The Parathyroid Glandules, Their Blood Supply and Their Preservation in Operation on the Thyroid Gland," by Halsted, an article which has been closely studied and much quoted. Halsted distinctly warns against interference with the parathyroid arteries, whether coming directly, as they usually do, from the inferior thyroids or from the channel. Ernst Hagenbach, in his valuable contribution on "The Function of the Thyroids and the Parathyroids," finds that injury or destruction of the parathyroid arteries of one side is followed by a passing tetany, then cachexia and death by cachexia; destruction of the arteries of both sides results in death in acute tetany; removal of the thyroid and of the inner parathyroids, saving the external ones produces no tetany but the development of cachexia; secondary removal of the external parathyroids causes death from tetany.

RELATIONSHIP OF THE DUCTLESS GLANDS.

Recent studies of the ductless glands or organs producing an internal secretion, hinting at the intimate interdependence of the thyroid, the parathyroids, the adrenals, the glandular part of the pituitary body, the liver and the pancreas, seem to show that the physiologic rhythm of the body demands the integrity of all. A pathologic condition of one of them calls for an attempt at a *restitutio ad integrum*—unless some other organ vicariously assumes its function — an attempt, aiming in fact at a therapeutic ideal, not reached by the method which removes or destroys.

Take, for an illustration, exophthalmic goiter. The thyroid has been proven to be a gland deserving to be ranked as a vital organ. The best results have been obtained, we all believe, by the removal of one-half or three-fifths or, with the saving of the parathyroids and their arterial supply, of nearly the whole of the gland. Injury to the parathyroids has been for a time atoned for by feeding with beef parathyroids, with Beebe-Rogers serum, or the transplantation of parathyroid tissue into the spleen, culminating in the beautiful and logical method of Halsted. Similarly, removal of too much of the thyroid has been counterbalanced by the administration of thyroid extracts or iodin-containing albumins.

NONOPERATIVE TREATMENT.

Measures other than operative may favorably influence some symptoms or the condition. A patient of mine, who was in a most miserable condition with a pulse of 190, delirium cordis, exophthalmos, loss of weight, and muscular tremors improved for a time by the application of ice to the neck and the region of the heart, by absolute rest, a diet free of meat, and belladonna administered for three weeks. The patient gained in weight, the exophthalmos improved, the pulse came down to 100. The patient assumed that he was almost cured. He returned to the hospital after two weeks in almost as bad a condition as before. A repetition of the above outlined treatment improved him sufficiently to prompt me to obtain a permanent result by an operation described later. We have not yet found the non-surgical treatment which gives satisfactory results, although Blum in a rather recent article asserts the opposite.

Professor Guthrie of Washington University, St. Louis, in whose experimental work on the vascular system I have been much interested, included in his experiments work on the thyroid of the dog, and a number of specimens show the results of the reversal of the circulation and the ligation of the arteries and veins. In ligating the veins of the thyroid in dogs he showed that at first, for perhaps three days, there results an edematous swelling of the gland, followed soon by reduction to the normal and finally a small reduction in size and a slightly increased firmness. The dogs then invariably gained in weight. With these proven facts as a basis, the following suggested itself to me. In exophthalmic goiter we have an enlarged gland, an enormous increase in vascularity and capillary dilatation, a multiplication of the thyroid cells with abnormal activity, the presence of a great number of indifferent or vagrant cells and a peculiar change of the thyroid gland cells—the whole condition resembling a reactive process without physiologic termination.

PASSIVE HYPEREMIA BY SURGICAL OPERATION.

The plan then adopted, tried on several dogs, one a goitrous one, gave the results expected. I then tried it on the patient before mentioned. The plan rests on the following proposition: Ligation of the thyroid veins produces dilatation of the capillaries with increased pressure, transudation of blood plasma through the endothelial capillary tubes into the extravascular spaces until the pressure of the plasma in the intercellular spaces equals the pressure in the capillaries. We might count on the escape of some extravascular fluid by the lymphatics. The effect of the transudate at first is a mechanical one; there is a crowding of the cells, an interference with oxygen admission, the retention of carbonic acid, an asphyxia. In this condition the vagrant or indifferent cells, the least fit to survive, suffer a degenerative process and die, while the limitation of arterial afflux brings the gland cells from hyperactivity to the normal. As part of the process the connective tissue stroma would increase and, in the later contraction, lessen the size of the gland—in other words, restore it to a condition near the normal. The result of the experiments on the dog distinctly demonstrates the success of the procedure, which in reality consists in the production of a Bier's passive hyperemia.

At a future time I shall publish the complete history of the case of my patient with observations during recovery and the final late effect. Objections to my suggestion may be made. At present I see one, surely not one to be regarded by the experienced operator; the infinitely greater difficulty of ligating the veins than the arteries. In my case I ligated both inferior thyroid and both superior thyroid veins. I am in doubt whether, on the right, I secured the trunk or only a large branch of the superior thyroid vein.

465 North Taylor Avenue.

DISCUSSION.

Dr. C. H. Mayo, Rochester, Minn., said that the study of the thyroid gland could not be dissociated from that of the parathyroid, thymus, pancreas and adrenal, and, probably, the pineal gland also. The thyroid had the most beautiful circulation in the body, with the exception of the brain; it would be impossible to destroy it except by deliberate act. At one time the thyroid undoubtedly delivered its secretions into the alimentary canal through a duct, and that was why the feeding of thyroid does so much good in some cases. Dr. Mayo said that Dr. MacCarty had made a classification comprising practically all goiters other than malignant; fetal thyroid; fetal activity; then, again, the normal gland activity; retention secretions; and then the degenerative conditions. So much had been written concerning the parathyroids that the surgeon, in any operation in the neck, feared that he might injure a parathyroid. Dr. Mayo said that in operating on over seven hundred goiters he had not had a single case of tetany. In 1896, in three cases, he had removed one parathyroid on the back of the gland. He did not know how many he might have taken out before that, but no symptoms were manifested in the cases where he knew that he had cut a parathyroid. Therefore, Dr. Mayo thought that the functions of these glands must be associated with other conditions. He did not believe that it was quite as serious to remove one of these parathyroids in the exophthalmic type of goiter as it would be in the old simple colloid goiter or diffuse adenoma. Dr. Mayo thought that the operation of ligation of the veins, producing passive hyperemia, which Dr. Tuholske had brought forth, was in the right line in certain cases. Operation was the rule in these cases of hyperthyroidism—and that was the term which should be applied to all of these cases.

Dr. Mayo said that the history of these cases and the classification of the disease from symptoms had been made without any foundation in fact. One spoke of Graves' disease, first described in 1835, of Basedow's disease, first described in 1840, or Parry's disease, first described in 1825. Two symptoms, exophthalmos and goiter, had been taken as of prime significance, whereas 80 per cent. of cases would present either one or both symptoms, and 20 per cent. might show neither the enlarged thyroid nor the exophthalmos. Proir to the appearance of these symptoms, Dr. Mayo said, these patients would be treated for heart disease. The nerve specialist would prescribe rest. The enterologist would call the case one of gastritis and enteritis, and order white meat of chicken and no oysters for the patient. Another treatment which Dr. Mayo said had been advocated was the injection of antitoxin. One might almost read the entire pharmacopeia to cover the history of the treatment of hyperthyroidism. If a patient with heart disease had protruding eyes, Dr. Mayo said, the case was diagnosed as exophthalmic goiter.

He said that ligation should be done in three types of cases. It should first be recognized that 25 per cent. of patients would recover with, without, or in spite of treatment. In very mild cases, which did not justify the removal of half the thyroid, a simple operation of ligating one or both superior thyroid arteries and veins should be done. Another type was so dangerous that there might be a degenerated heart muscle, possibly brown atrophy with soft spleen, with nephritis albumin in urine, and fatty degeneration of liver. The physician might be afraid to operate. If under cocain anesthesia, ligation of first one artery and then the other, with the accompanying vein were done. Dr. Mayo said, the patient would improve. In another type of cases the right and middle lobe would perhaps be extirpated and the patient would improve; if there was insufficient improvement, or a relapse, it should not be considered a mistake to have operated on that thyroid. Ligation of the superior thyroid artery and vein on the other side would have a remarkably good effect in such cases.

Dr. Mayo said that last January he and his colleagues had gone over the last 200 cases of exophthalmic goiter and sent out 190 letters. (Ten patients, 5 per cent., had died from operation.) They had received 167 answers to these letters. Seventy per cent. of the patients were cured, and 89 per cent. had either been cured or greatly improved. A few more cases brought the percentage up to 94 per cent. cured, greatly improved or somewhat improved. Some were not improved at all. In some cases, Dr. Mayo said, surgery could do anything but many of these cases were treated so long medically that the burden of surgical mortality was of necessity much greater than it should be; it ought to be called medical and surgical.

Dr. A. J. Ochsner, Chicago, said that there was no operation in the entire field of surgery in which the importance of knowing when and how was greater than in this particular operation for exophthalmic goiter. The surgeon did well to operate when the patient's condition was at a standstill or, in general, reasonably good, so that resistance to the slight shock of operation might be counted on. When there was no resistance left, the results of operation would be exceedingly bad. Dr. Ochsner mentioned another class of advanced cases in which the other organs of the body still were sufficiently good, so that if the patient's temporary condition were improved the immediate, as well as the late result, would be good because the absorption of the thyroid secretion would be stopped. Recovery, however, would be slow. Dr. Ochsner said that much had been learned from Kocher, Mayo and others; namely, that in the operation itself the patient could be protected, first, by reducing the trauma; second, by preventing shock, especially in cases which have gone too long before operation, and by performing preliminary operations in these cases, such as Dr. Tuholske and Dr. Kocher had recommended, or by following the method of Charles Mayo, of dividing the operation into two stages. There was no operation in surgery that had improved so much during the last ten years, both as regards the choice of time and the number of operation as this one.

CASES OF VERY GENERALIZED POLYNEURITIS.*

PHILIP ZENNER, A.M., M.D.
Professor of Neurology in the Medical College of Ohio, Medical Department of the Cincinnati University.
CINCINNATI.

The purpose of this paper is to present two cases of polyneuritis, which, so far as I know, present features which are unusual and appear to me to be of much interest. In the first case the patient had the added distinction that he had two attacks, in some respects alike, at intervals of thirteen years.

Case 1.—*History.*—A. R., aged 13, of a healthy family, was seen Jan. 3, 1891. He gave a history of having ached all over for four weeks, of his face being drawn to the left side for three weeks, and of pains in his face and limbs.

Examination.—When I saw him he still suffered sufficiently to disturb his night's rest. He had double facial paralysis. The upper and lower branches of the seventh nerves were affected, but the paralysis was not complete, as the eyes could be feebly closed. The electrical reaction of the facial muscles were those of degeneration—loss of faradic contractility, "tardy" reaction to the galvanic current, with the normal formula reversed. The patient also had an unsteady gait. The muscles of the legs were weak but not distinctly paretic. They responded to faradic electricity, but only to a rather strong current. The knee jerks could not be elicited. The urine was normal; sensation, special senses, disks, pupils, etc., were normal. The patient gradually improved.

March 28: It was noted that the facial paralysis had disappeared on the left side and nearly so on the right.

May 25: A note stated that the patient was well, but the knee jerks could not be elicited.

The patient now remained in good health for 13 years, though in 1896 he was examined merely for the purpose of learning the state of the knee jerks, and they were found to be normal.

Subsequent Examination.—I was called to see him again Oct. 20, 1904, on this occasion in consultation with Dr. Stephen E. Cone. Some ten days prior to this date he began to suffer with aching in his back and legs and, about a week later, with weakness in the legs and face. When I saw him he had a good pulse and normal temperature, but a heavily coated tongue, no appetite, and could not sleep on account of his general distress. He now had complete double paralysis, the muscles presenting the reaction of degeneration. He was weak on his feet so that he could scarcely walk. The knee jerks and Achilles tendon reflexes could not be elicited. The plantar reflexes were present, though slight, and normal, that is flexion. There were no other objective symptoms. For some time the subjective symptoms were, so to speak, the predominant ones. His suffering, aching, pains, etc., was very great, so that with hypodermic injections of morphin and hypnotics he scarcely obtained any relief, and very little sleep. But at the end of about three weeks the subjective symptoms left him, and thenceforth he slept without the aid of drugs. In the meantime his paralysis had steadily increased, reaching its acme about the time the subjective symptoms ceased. A few days after my first visit he was altogether unable to walk.

November 8: Patient could flex and extend toes fairly well; plantar flexion of ankles was quite weak, dorsal flexion nil, extension of knees nil, flexion and adduction quite weak, abduction stronger; hips weak but stronger than the knees. The right leg was a little stronger than the left. The muscles responded to the faradic and galvanic current, but it required a very strong current to produce contraction, especially of the quadriceps. (At a later period the leg muscles most profoundly paralyzed failed to respond to either faradism or galvanism, a fairly strong current having been applied.) Sensation in legs was very slightly blunted. The patient spoke of the bladder and rectum being weak, though there was no retention nor incontinence. This was complained of for but a short time. The patient began slowly to improve, but about December 20 he suddenly got worse, the paralysis increasing beyond what it had been before, and for a short time there were also subjective symptoms.

Jan. 8, 1905: Patient called attention to the fact that the left deltoid was slightly paretic, but this condition was of short duration. It was noted on this date that for several weeks some power of voluntary movement had been observed on the right side of the face, and for several days on the left side, and that he furrowed the brow quite well.

May 28: Two weeks previous to this date he began walking with the assistance of two helpers and at this date he could walk with only the assistance of a cane, but it was with the "steppage" gait, especially noticeable on the left side, the right leg being the stronger. The larger number of muscles had considerable strength. The most decided weakness was in the dorsal flexors of the left toes, extension of the big toe being almost nil. There was some sense of numbness in the left foot. The appearance of the face was not far from the normal.

August 22: Patient could walk up and down stairs unassisted. Chief weakness was in dorsal extensors, ankles and toes. Knee jerks, Achilles tendon reflexes and plantar reflexes could not be elicited.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

September 13: Gait was still improving. Still slight impairment of tactile sensation of left big and little toe. Face still felt stiff and looked unnatural when he laughed. He could not expose upper teeth—paresis of upper lip. When he ate, tears frequently overflowed.

Jan. 15, 1906: Not much change in the face, but the facial muscles responded to faradism. It is well to note that the electrical reactions appeared to be normal, while voluntary control of the muscles had not yet become fully restored. He had an elastic, natural gait, but said he could not run.

February 5: Knee jerks were present, but no Achilles, nor plantar reflexes.

August 3: Knee jerks and Achilles reflexes were present, slightly more marked on the right side. No plantar reflex. Only noticeable defect was that the upper lip and dorsal extensors of toes and ankles had not regained their full strength.

I will again briefly refer to the more striking features of this second attack. The progress for several weeks was steadily from bad to worse, almost as steady as the movement of the clock, and the same was true of the improvement after it had once definitely begun. It was about a year after the onset of his illness that the patient again began to attend his business, and in about one and one-half years he was practically well. It is worthy of note that such extensive and profound paralysis should have left practically no traces.

The paralysis of the legs began in the muscles that move the large joints and only finally affected the toes, and it was in the latter that the paralysis was of longer duration. This is not the history of ordinary multiple neuritis, that is, the paralysis usually begins in the distal parts of the extremities. It is a rule, too, that the muscles first affected are last to recover.

The condition of the reflexes is noteworthy. At the very first examination the knee jerks and Achilles tendon reflexes were abolished, but a normal plantar reflex was present. The latter soon disappeared. It was more than one and a quarter years before the knee jerks returned, and some months longer before the Achilles tendon reflex was found. Even then the reflexes were probably not altogether normal, for they were more marked on the right side—the side which had been less affected—than in the left. The plantar reflex was absent in August, 1906.

The distribution of the paralysis also was unusual. While in multiple neuritis the four extremities are commonly affected, in this case, though the paralysis was extensive and profound, the upper extremities practically escaped. The double facial paralysis, though observed in cases of multiple neuritis, is rare. That there should have been so little anesthesia with such extensive motor paralysis is also uncommon.

With all its unusual features there is no room for doubt of the correctness of the diagnosis. The extent, profoundness and duration of the paralysis, the electrical reactions and full recovery all establish that. The most striking fact is that there should have been two such attacks in the same individual. There was no known cause for either attack, and they were assumed to be due to the grip.

Case 2.—*History.*—Dr. T., aged 29, good family history, good habits, always had good health, never had venereal disease, was an athlete at college. Had been married three years and had a healthy child, one year of age. For six months before his illness he had much worry and mental strain on account of illness in his family and other troubles. The month before he became ill he was very hard worked, and lost much sleep. One warm night, perspiring and exhausted, he threw himself on his bed without clothes or cover, fell asleep, and awoke the next morning chilled through, the temperature having fallen decidedly, and the cold wind blowing on him. He had had some severe pains in the back of his head for about a week prior to this time, possibly due to want of sleep, but he attributed his illness to this chilling, for his aching began immediately thereafter. I saw him July 5, 1907, in consultation with Dr. Ambrose Johnston, three or four days after his symptoms began. He suffered much with aching in his limbs and trunk, and was, therefore, moving constantly from side to side. So great was his suffering that he had just received a hypodermic injection of morphin. For a couple of days he had noticed that he was getting gradually weaker in his legs, and when seen observed that his hands and arms were getting weak. He also had paresthesia, numb, cold feelings, in the distal parts of the upper and lower extremities.

Examination.—On examination his pulse and temperature were found to be normal. Excepting that he was weak in his feet, there was no manifest paresis. All qualities of sensation, tactile, stereognostic, etc., appeared to be normal. Knee jerks and Achilles tendon reflexes could not be elicited. Pupillary reflexes were normal. Plantar reflexes were normal. The patient's condition now steadily grew worse. Four or five days after above date there was manifest paresis of shoulders, hips and knees.

July 12: Patient could not move the arms at the shoulders, nor the legs at the hips or knees, and there was considerable paresis of hands and feet. There was bilateral facial paresis. He had very little power in the muscles of the mouth and cheeks or in the orbicular palpebrarum, but he could furrow his brow well. His voice often became husky so that it was difficult to understand him, and he complained of accumulation of mucus in the throat, which it was difficult to remove. He required strong cathartics, and, at times there was weakness of the sphincter ani. He complained bitterly of paresthesia of the hands and feet. There was tenderness over the sciatics, also in other parts. He could not bear to have the legs extended, because, he said, it seemed to stretch the sciatics and it gave him extreme pain in them. There was still no manifest anesthesia. The paralyzed muscles responded to the faradic current. Plantar reflexes were normal. The patient had been closely watching his symptoms from the beginning. Probably partly from this cause, partly from his suffering, he was in an extremely emotional state. His condition continued to get worse, the power in the muscles of the extremities and face became less, his voice feebler, the accumulations in the throat more annoying and more difficult to remove, swallowing finally impossible (at times, the fluid in his throat would escape from his nose), so that from July 18 he was fed altogether through the stomach tube. About this time for several days he had some fever, highest 102 F. when his pulse was 140. At this time his physician believed, on account of his manner of breathing and all, that he was about to die. Soon after that his condition began to ameliorate somewhat, probably due in part to his receiving sufficient food, which had been taken in very small quantity prior to this time.

July 25: There was almost absolute paralysis of the four extremities, no abdominal, cremasteric or plantar reflexes. Strength of abdominal muscles seemed normal. Some impairment of sensation. Astereognosis in both hands. Patient had no stools without the aid of drugs and the nurse had to use his fingers. There were variations in the facial paralysis, one day eyes was somewhat restricted, especially in an outward direction, and the patient spoke of occasional double vision.

August 5: Decided anesthesia noted in hands and feet, and lower parts of arms and legs, and astereognosis. There was more marked paresis of the left abducens. There was very little power manifest in the left hand and elbow and right fingers. There were variations in the facail paralysis, one day one side of the face would be more paralyzed, the next day the other; the one day he could not furrow the brow, the next day he could furrow it. Accumulations in the throat had ceased, and patient could swallow saliva better, but still used the stomach tube.

August 15: Could swallow well; discarded stomach tube a week previously. Strength of upper extremities had increased, some power of movement in all the joints, minimal power of movement observed in feet. Facial paralysis less.

August 26: Fair strength in muscles of face and upper extremities. In lower extremities some power manifested in muscles above the knees, none below. Still anesthesia of feet and hands. Movements of eyes better, but still somewhat limited.

September 7: Movement of eyes and muscles of face normal. Hands stronger. Some power manifested in all the muscles of lower extremities. Tactile sensation everywhere was fairly good. But there was some astereognosis; impairment of muscular sense and ataxia in the hands.

October 2: Strength of muscles and all qualities of sensation appreciably normal, excepting some weakness of the anterior tibial and peroneal groups of muscles, and slight impairment of sensation over the little toes. Knee jerks and Achilles tendon reflexes absent. Plantar reflexes could not be properly examined because of great sensitiveness of the soles of the feet.

November 21: Had been at work again for the past three weeks. Discarded a cane one week previously, walked well, and could run and jump, but not well. Some patellar tendon reflex present—occasional response. No Achilles tendon reflex. No plantar reflex. He still had numb tingling sensation on the dorsum of the feet, and occasionally in the fingers. There was also hyperesthesia of the feet, so that he could scarcely touch them without distress, and he could barely stoop to take off his shoes because it caused a pain in thighs and hips. His greatest complaint was that it took so long to fall asleep at night.

I examined him some six months later. His reflexes were normal, and he had been feeling quite well for several months.

This case can scarcely be considered otherwise than as one of multiple neuritis. Its manner of development, marked sensory symptoms and complete recovery after the extensive paralysis presents a clinical picture altogether unlike that of poliomyelitis anterior. In the recent epidemic of poliomyelitis in New York cases were reported which were very different from the ordinary disease, cases with very pronounced and widespread paralysis, presenting cerebral as well as spinal symptoms, in which there was speedy and complete recovery. But these cases appeared to be altogether in young children, and in addition to the fact that no epidemic cases appeared in Cincinnati the history in this case differed in many essentials from those just referred to.

Apart from the very widespread paralysis this case is certainly striking in many ways. The degree of suffering was excessive, even for a case of multiple neuritis. It was the earliest symptom and remained to a degree after other symptoms were practically gone. The sensory paralysis, the anesthesia, considering its extent and degree, was very late in its appearance. It, as well as some of the pains and motor paralysis, was rather sudden in its disappearance. The patient had always been a healthy man and came from a healthy family, but the manifestations last mentioned as well as some others made it appear that there might be no inconsiderable hysteric element in the case.

The electrical tests of the paralyzed muscles were not altogether satisfactory. His suffering and sensitiveness were such that usually no satisfactory examination could be made, but on several occasions some of the paralyzed muscles failed to respond to a strong faradic current. The comparatively early recovery of the muscles makes it probable that there had been no great changes in the electrical reactions.

As in the first case reported, the pronounced paralysis was first observed at the large joints and not in the distal parts of the extremities, as usually occurs in multiple neuritis.

DISCUSSION.

Henry W. Freudenthal, of New York City: I would like to ask whether iodide of potassium was used in either of the cases reported, and whether there was a history of syphilis and what the reactions were?

Dr. Zenner said in reply to the question that there was no iodid given in the cases, and no syphilis found. There were the usual manifestations of reaction of degeneration in the muscles of the face while in the lower extremities a very strong current failed to produce any contraction in some of the muscles in the first case. In the second case the examination for electric reactions was unsatisfactory on account of the pain which it produced. At times, with the current strong, no reaction whatever was obtainable. But inasmuch as there was complete recovery in a comparatively short time, the chances were that there were no considerable changes in electric reactions.

PATHOLOGY IN DENTAL COLLEGES.*

L. G. NOEL, M.D.
NASHVILLE, TENN.

Believing the course of study in pathology in dental schools defective in many respects and that it has not occupied the high place in the curriculum of study that its importance deserves, I conceived the idea of addressing a letter of inquiry to the various dental colleges in America. This was done with a view to comparing the methods pursued in this study, and with the hope of ultimately arriving at some improvement in teaching, perhaps causing the adoption of a uniform course of study. The body of the letter follows:

> Wishing to acquaint myself with the methods employed in the leading dental schools in teaching dental pathology, and to ascertain to what extent students are taught the general principles of pathology in these colleges, I address you this letter, begging that you will kindly reply at your earliest convenience, setting forth as briefly as possible the methods pursued, in your school, in teaching this branch, the text-books employed, the extent of your requirements in examination, etc.
>
> Believing there is need of improvement in the teaching of this important branch in nearly all of our dental schools, I am seeking by a comparison of methods to arrive at some correct conclusions about needed reforms. After stating briefly what you are doing in this teaching, I will thank you to point out also the improvements you conceive to be needed.

Forty-three letters brought twenty-five replies, a result showing, I think, a lively interest in the subject, especially when we consider that these inquiries were made during the month of January at the busiest part of the term and that the answer entailed considerable painstaking labor.

It would be instructive to reproduce all these letters here, especially as they come from the most eminent writers and teachers in our profession, but to do this would take up too much time and space, and I must try, therefore, to give briefly the salient points gleaned from this correspondence.

In several instances I wrote a second letter to draw out my correspondent more fully, to call attention to a question he had omitted to answer, or to ask another. Many of my correspondents sent carefully prepared syllabi of the course of study in pathology in their respective schools and these will be very useful in formulating a uniform course. It is apparent from these letters that very little laboratory work in biology, bacteriology and pathohistology is being done in our colleges, for the simple reason that we lack time for any satisfactory pursuit of such work under the three years course. Several of our more important colleges were planning to construct laboratories, and to commence such a course when the brief period of the four years course was so suddenly terminated. Several of our schools are doing some work in pathohistology in connection with the studies in biology, bacteriology and histology, but this work is necessarily defective for want of time. There can be no question of the value of this method of teaching pathology. The student should pursue here the same methods of study as in anatomy, chemistry and histology, a practical training in laboratory processes.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Two letters from Dr. G. V. Black and two from Dr. James Truman show how these eminent teachers have labored under the difficulties caused by lack of time to give the training each felt so important for the life work of the dentist. Dr. Black in his reply to my second letter says:

DR. BLACK'S REPLY.

I have read your letter of February 13 with some care, and will say that in bacteriology, which is part of my own subject, one of my assistants, Professor Willard, doing the work, three hours a week are given to laboratory work during the whole year. There is quite a little done in the histologic laboratory in the pathology of the teeth, but the laboratory work in general pathology, and also in physiology, is not up to the standard that I should like to have. This is not because we have not room, or anything of that kind, but simply because we have not the time in our course to do that work. When it was arranged that we should have a four years' course, we were building, and I had planned for a physiologic laboratory and a pathologic laboratory for general pathology; but, as we did not get the time—the four years—we have been compelled to leave them out. I hope some of these days to be able to do this work; it ought to be done in every dental school.

Replying to a second letter of inquiry on this subject Dr. James Truman first calls my attention to his "Annual Fasciculus," which he sent me, in which is outlined the pathologic work in his school; then he says:

DR. TRUMAN'S REPLY.

You ask me for my opinion of "How to make the best of this work in the three years allotted us?" Each school naturally deems its plan the best with the limited time given. I must repeat that dentistry, and all branches included in that name, can not be taught in three years. At the best the student acquires a superficial idea of the work, and must depend on experience to fill up the lost spaces. When our department came under my care in 1883 I tried to bring to bear the experience of twenty years in another school. The guides were not many, and most of these were antagonistic to my own views in regard to teaching. This period was that which fell on dentistry between the old skilled mechanical metal workers and the unskilled rubber operators. In these years dentistry lost much, in fact, the working of the noble metals was practically a lost art. I felt that this should not be permitted, and that it must be taught, as the time would come when that skill would be needed. To accomplish this, I organized technical branches in the mechanics and operative in the freshman year. Having no guides, for these were not, I think, generally established, the beginning was somewhat crude, teachers had to be trained. Since then this original idea has been expanded until the first-year men now must go through the whole process from the making of metal work, etc.; and in the operative, from the beginning, an art student having charge of the modeling. The freshmen, as a rule, do not come to the living patient during the year.

The course thus subdivided between the three years, for it is extended in part over all, works as well as could be expected, and now that gold is so much used for crowns and bridges, as well as the base for artificial dentures, I feel that my earlier efforts in this direction have had full fruition. I do not wish to be understood as claiming any special original credit for the technic work; this seems to come as a spontaneous need, perhaps not as I saw fit to start it.

The announcement sent you will explain the amount of time given to each branch, and I think it must be evident that the association of faculties made the mistake of its life when it killed the four years' course. The undergraduates reach the third year with much of mechanical, as well as theoretical knowledge, but with the operative largely theoretical. With some, I need not say to you, this may be sufficient, but the large majority have knowledge without skill. This is true of every school in the United States, in my opinion. In order to secure something of every study every one must be limited to a certain number of hours, and the test of knowledge must be examinations. If any set of teachers have been able to reduce this to an exact science I am not acquainted with them. To make the three years available, the subjects must be cut to fit the time. I am utterly opposed to the method, whether in our own school or any other. I will not live to see five years in undergraduate life, but I sincerely hope that the time will come when a dentist will be required to take as many years to study this complex profession as a bricklayer takes to lay brick. I do not know that I have answered your query, but perhaps you can glean something from it.

Surely we shall glean much from the statements of this earnest and conscientious teacher, who thus so frankly states the difficulties under which he has labored. It is probable that Dr. Truman's letter suggests these questions: What has the gold work in dental college to do with the study of pathology? Why does not Dr. Truman speak to the subject and answer briefly the query above quoted? Why do I reproduce so much of a letter that is apparently not germane to the subject? I will try to answer these questions and make my position plain.

Dr. Truman has for years been engaged in the practice of dentistry, in teaching dentistry, and in contributing to the literature of dentistry. He has not lived for selfish ends, but has endeavored most conscientiously to impart to his students the things needful to fit them for the practice of dental and oral surgery. Dentistry is a peculiar profession. It is unlike any of the other specialties of medicine, in that it is a texture made up of a warp of scientific facts with a woof of mechanical skill and handicraft. You can not separate the woof from the warp and maintain the integrity of the fabric. That Dr. Truman views the subject in this light is evidenced in this second letter from which I have quoted. It is difficult to bring the old practitioner to see the question in any other light, and especially is this true of the faithful teacher who knows what is required of him, and has personally felt the responsibilities the student must meet when he leaves the college and goes out to practice.

Feeling the importance of this practical training, as well as the need of the scientific knowledge as a foundation, Dr. Truman has endeavored to show how he has battled with these difficulties as best he could, trying to impart the most fundamental truths of each study in order that the student may continue his studies after graduation.

THE CAUSES FOR CRITICISM.

Dental colleges are often severely criticised by members of the profession who are not engaged in teaching, and who are therefore not familiar with the many and various difficulties that must be encountered. The arraignment is especially severe that so much time is devoted to mere mechanical training, to the operatory and prosthetic laboratory to the neglect of more important fundamental scientific studies.

This complaint, it must be admitted, is just; it is an evil that should be remedied. We all admit that, but we do not yet see our way to correct it. It is not a new complaint, for the trouble commenced in our two oldest dental schools shortly after they were founded. I remember seeing, years ago, somewhere in our literature as coming from Dr. James Taylor, this same complaint: that it was always difficult to get the students to leave the practical work of the operatory and laboratory, and attend regularly the lectures on the five fundamental scientific studies. Thus, it has, on account of the texture of our cloth, if I may be allowed to return to my simile, been ever with us from the beginning down to the present day, the same difficulty, except that it is growing.

We have lengthened the course of study but one year since the founding of the earliest dental schools, and this increase of time is utterly out of proportion to the growth of scientific knowledge, to the addition of biologic, histologic and bacteriologic lore, not to mention *other things, that must be taught.*

It is important now, as it was in the days of Chapin A. Harris and James Taylor, for the dental student to acquire manual skill. He comes to us for that, and when we send him forth from our colleges we give him a diploma which states to all the world that he is competent to practice the science and art of dentistry.

Why need we fall into the error of taking a one-sided view of this subject? We must not neglect those scientific studies which are the foundation of our art. Science is the foundation of all art, for painting, sculpture, music, architecture, etc. The painter must be an anatomist if he would portray the human form, the sculptor must be an anatomist if he would produce in marble the divine effigy.

SCIENCE OF FIRST IMPORTANCE.

Then if science is the foundation for our art it must necessarily take first place. If the time is too short for the needed study at school, and aught must be left unfinished, it must not be the foundation on which our superstructure is to rest; this must be securely laid that the building may be placed thereon, not hurriedly and defectively, but by gradual and careful accretion, until it stands complete, skilfully wrought, a thing of beauty.

Thus we dream of our work as teachers, but of how many educations commenced in our classes do we see even the foundations fairly completed? As teachers we must, for lack of time, as has been pointed out by Drs. Black and Truman, try to teach something of all the essential fundamental sciences, though giving but a superficial and unsatisfactory training in each. We must try to economize the student's time, working together to this end, eliminating from our requirements all useless technic work and substituting in its place such scientific training as we deem more important.

In the light of the recent great and brilliant contributions to our knowledge of pathology by such men as the late Dr. W. D. Miller, and our own beloved Dr. Talbot, I think I need not urge that our students should be taught as much pathology as possible while they are in the formative undergraduate state.

Whatever must be slighted in the preparation of our students for practice, it must not be these great studies on which the ability to recognize disease must depend. How can we hope for the application of intelligent therapeutic measures, or the inauguration of effective prophylactic treatment, without a knowledge of etiologic and pathologic conditions?

We must all admit that in many of our schools much time is consumed in technic work, which if not useless, is at least of minor importance when compared to the study of pathology. A dentist may be an operator of the rarest skill, but if without pathologic training he will be a failure as a practitioner, because he is without diagnostic discernment, without guides for the application of his skill. The infirmary is the best place to teach the application of the principles of pathology, and the student should be admitted early to the operatory for the acquisition of this training. I shall not attempt to say how early students should be admitted, that question must be decided by each school according to its own peculiar conditions, but it is clear to me that students should enter the operatory during the junior year.

Here we must show the student how to recognize the beginnings of systemic disease by its manifestations in *the oral cavity, teach him how to arrive at correct conclusions* and how to apply the various prophylactic and therapeutic measures available to the practitioner.

I must confess that at the time of this writing my thoughts in these subjects may be influenced and on some points at issue intensified somewhat by recent criticisms on dental education that have appeared in our journals. This is why I am endeavoring to show the peculiar features of dentistry as a profession even at the risk of tedious prolixity.

AN UNFAIR COMPARISON.

Our critics are comparing our methods with those pursued in medical schools, drawing therefrom conclusions unfavorable to us. The conditions to be met, the pursuits to be followed are very different. We must prepare our students to take up and practice a branch of surgery that is so exacting in its demands for manual skill that our state boards, many of them, require the candidate for a license to practice to perform certain operations in the presence of the examining board, which work is graded by the board and becomes an important factor in fixing his standard and deciding his fate.

Are such methods pursued by medical boards? Is the candidate for license to practice medicine and surgery required to amputate a limb, to ligate an artery, to operate for appendicitis, or to meet a crisis of any kind in medical practice? No, he may be asked how he would do these things, but is never actually required to perform the operations.

The state boards of examiners are made up of men many of whom obtain their appointments not because of mental and professional qualification for the place, but merely through political preferment, and regardless of their fitness for this work. Many of them are so ignorant that they could not themselves answer correctly one-half the questions they put to the candidates who come before them, yet these are the very men who are most severe in their criticism of dental colleges.

THE PROBLEM TO BE MET.

We must prepare our students to encounter these state boards, and when they fail before them we are censured for the failure. This explains why so much time is devoted to the mechanical and the manual, often to the neglect of the mental culture of the dental student.

We must prepare the student not only to pass the state board, but to commence practice, to compete with the old practitioner to earn his livelihood. We owe to him all this, it is what he comes to us for and what we have promised him. It is in most instances what he sadly needs, for seldom has he a large fund of available cash on hand at graduation.

We find ourselves as teachers navigating a stormy sea of criticism betwixt Scylla and Charybdis. Some of our critics are clamoring for all science, others seem to be for all technic and infirmary practice. We know that these things are to each other as the right hand is to the eye; that one cannot say to the other, "I have no need of thee." Fair science is the handmaid of art; science may be said to be the eye itself, but art is the right hand.

Then let us proclaim a truce to carping criticism and look the field over reasoning calmly together for betterment. The first step toward a remedy is clear and it is our duty as teachers to take it without delay. We must endeavor to bring the National Association of College Faculties to return to the four years' course, and if we fail in this effort, then I am in favor of making an appeal to all schools of dentistry of good standing in the United States, whose faculties are willing to lay aside all selfish motives and work for a high standard, to withdraw from the association and form a new organization which will adopt a longer course of study and inaugurate such other reform measures as we may deem necessary.

Some points brought out in my correspondence I hope to have further elucidated in the discussion of the subject. These relate to the preparation of the student for the taking up of this study, the order of this preparatory work, the time when the study of pathology shall actually commence and the order in which it shall be pursued.

DISCUSSION.

Dr. Eugene S. Talbot, Chicago: I agree that a four or five years' course is necessary; yet improvements can be made and should be made at the beginning of the next course President Eliot of Harvard recently stated that there is no necessity of the student's taking four years to do the work that could be done in three. There are men who graduate from Harvard in three years. In the dental school considerable obsolete material, now used for padding, could be cut out of lectures. Considerable time is wasted by students for want of system and opportunity to fill all the hours. Students entering dental schools should be required to graduate from high schools in which are taught physics, chemistry and biology, the last including zoology, which also includes evolution. Dentistry can not be taught to-day without these studies.

Medical schools devote three or four years to all the other specialties of medicine while the dental school spends the entire three years on one specialty. Subjects of the most vital importance to the dentist are omitted or only hinted at and of these he is entirely ignorant when he begins practice. First and most important of these is oral hygiene. Cleanliness should be the religion of the institution in which the student receives his instruction. This method naturally requires that the teacher and building be kept as cleanly as the surgeon and his operating-room. The first lesson taught the student in the clinic before operating on patients should be to place his own mouth in an hygienic condition as well as the patient's.

Most teachers discourse on diseases of the gums and alveolar process as pyorrhea alveolaris. It is an impossibility to teach students the pathology of these tissues under such a name After the student learns what the term means he is all at sea when the different stages of inflammation are met with. He must always look for pus and if no pus is present, there can be no "itis." I do not care whether the disease is called interstitial gingivitis or alveolitis; both are good terms. The term pyorrhea alveolaris should be used when pus is present. Few teachers on orthodontia give an intelligent course on etiology of deformities of the jaws and irregularities of the teeth. Another great mistake of some teachers is the invention of a new pathology to fit some particular mechanical hobby to advertise themselves. What is needed in dental schools is a better educated class of teachers to give a broader course.

Dr. M. H. Fletcher, Cincinnati: We are not all blessed with patients who can or will pay for services rendered by a physician or highly skilled stomatologist to treat diseases of the mouth. What are these people to do? Let us put ourselves in the position of some poor fellow who has no money to pay except for extraction and for a set of store teeth when the natural teeth are all gone. I have for years been an advocate of advertising dental offices, provided they have men to do this kind of work properly. Were we to have none but the highly educated practitioners, the probabilities are that many people would have to go without treatment and become toothless; or else men capable of more successful careers than those promised here, would necessarily deteriorate into that kind of practice at a very small price. On the other hand, there is a large clientele requiring what most of us can not give—treatment from the most highly skilled men that can be had, trained in anatomy, histology, pathology and diagnosis. I am thoroughly in accord with Dr. Talbot as to the failure in most of our dental colleges to teach pathology adequately in preparation for the practice of stomatology. Nomenclature is a point which has caused me a great deal of chagrin at times. Medical men say, for example, "You do not have in the text-books any description of the disease known as pyorrhea alveolaris." I would advocate every method that can be adopted to increase the knowledge of our students in the line of pathology and the treatment of disease.

Dr. M. L. Rhein, New York: I agree with Dr. Talbot as to the necessity for a generally better education, both of the teacher and student. Until we reach the same educational plane that practitioners in general medicine must attain, it is absurd for dentists generally to speak of dentistry as being on an equal footing with general medicine.

The subject of the teaching of pathology is one on which I feel very strongly. It is almost impossible to teach pathology of a part of the body until the student has not only had proper instruction in, but has shown by his examinations a proper understanding of, general pathology.

Dr. N. S. Hoff, Ann Arbor, Mich.: The teaching of the subject of pathology is difficult, and I do not think it all depends on the extent of the student's preliminary education, neither does it depend altogether on the education of the teacher. Sometimes a student who is not what we call well educated gains a good understanding of pathology. On the other hand, a student with the very best recommendations, may disappoint us by turning out to be an inferior student. I hesitate to criticize the attitude that the dental colleges have taken towards the matter of preliminary education.

Vida A. Latham, Chicago: Pathology comes a little too early in the present course of instruction. Pathology presupposes and accepts a knowledge of everything gone before; it takes in physiology, anatomy, general medicine, general pathology, surgery, etc. When we get it in the first and second years, as we do in many schools, it is difficult for a teacher of pathology to get the student to understand and make the references to all classes of work. A teacher gives a few points to learn by heart, and as a rule the student is not required to learn anything outside of that. I think the system of teaching in Michigan University some years ago, which required the student to look up branch or essay subjects, was one of the best incentives to a student to obtain a broader education in dentistry.

The literature of pathology, written by medical men as a rule, unfortunately, does not apply to conditions of the mouth particularly, as the tumors and pathologic conditions of the mucous membrane, the salivary glands, lymphatics of the mouth, etc., are not sufficiently known. I doubt if any one

This complaint, it must be admitted, is just; it is an evil that should be remedied. We all admit that, but we do not yet see our way to correct it. It is not a new complaint, for the trouble commenced in our two oldest dental schools shortly after they were founded. I remember seeing, years ago, somewhere in our literature as coming from Dr. James Taylor, this same complaint: that it was always difficult to get the students to leave the practical work of the operatory and laboratory, and attend regularly the lectures on the five fundamental scientific studies. Thus, it has, on account of the texture of our cloth, if I may be allowed to return to my simile, been ever with us from the beginning down to the present day, the same difficulty, except that it is growing.

We have lengthened the course of study but one year since the founding of the earliest dental schools, and this increase of time is utterly out of proportion to the growth of scientific knowledge, to the addition of biologic, histologic and bacteriologic lore, not to mention other things, that must be taught.

It is important now, as it was in the days of Chapin A. Harris and James Taylor, for the dental student to acquire manual skill. He comes to us for that, and when we send him forth from our colleges we give him a diploma which states to all the world that he is competent to practice the science and art of dentistry.

Why need we fall into the error of taking a one-sided view of this subject? We must not neglect those scientific studies which are the foundation of our art. Science is the foundation of all art, for painting, sculpture, music, architecture, etc. The painter must be an anatomist if he would portray the human form, the sculptor must be an anatomist if he would produce in marble the divine effigy.

SCIENCE OF FIRST IMPORTANCE.

Then if science is the foundation for our art it must necessarily take first place. If the time is too short for the needed study at school, and aught must be left unfinished, it must not be the foundation on which our superstructure is to rest; this must be securely laid that the building may be placed thereon, not hurriedly and defectively, but by gradual and careful accretion, until it stands complete, skilfully wrought, a thing of beauty.

Thus we dream of our work as teachers, but of how many educations commenced in our classes do we see even the foundations fairly completed? As teachers we must, for lack of time, as has been pointed out by Drs. We find ourselves as teachers navigating a stormy sea of criticism betwixt Scylla and Charybdis. Some of our critics are clamoring for all science, others seem to be for all technic and infirmary practice. We know that these things are to each other as the right hand is to the eye; that one cannot say to the other, "I have no need of thee." Fair science is the handmaid of art; science may be said to be the eye itself, but art is the right hand.

Then let us proclaim a truce to carping criticism and look the field over reasoning calmly together for betterment. The first step toward a remedy is clear and it is our duty as teachers to take it without delay. We must endeavor to bring the National Association of College Faculties to return to the four years' course, and if we fail in this effort, then I am in favor of making an appeal to all schools of dentistry of good standing in the United States, whose faculties are willing to lay aside all selfish motives and work for a high standard, to withdraw from the association and form a new organization which will adopt a longer course of study and inaugurate such other reform measures as we may deem necessary.

Some points brought out in my correspondence I hope to have further elucidated in the discussion of the subject. These relate to the preparation of the student for the taking up of this study, the order of this preparatory work, the time when the study of pathology shall actually commence and the order in which it shall be pursued.

DISCUSSION.

Dr. Eugene S. Talbot, Chicago: I agree that a four or five years' course is necessary; yet improvements can be made and should be made at the beginning of the next course President Eliot of Harvard recently stated that there is no necessity of the student's taking four years to do the work that could be done in three. There are men who graduate from Harvard in three years. In the dental school considerable obsolete material, now used for padding, could be cut out of lectures. Considerable time is wasted by students for want of system and opportunity to fill all the hours. Students entering dental schools should be required to graduate from high schools in which are taught physics, chemistry and biology, the last including zoology, which also includes evolution. Dentistry can not be taught to-day without these studies.

Medical schools devote three or four years to all the other specialties of medicine while the dental school spends the entire three years on one specialty. Subjects of the most vital importance to the dentist are omitted or only hinted at and of these he is entirely ignorant when he begins practice. First and most important of these is oral hygiene. Cleanliness should be the religion of the institution in which the student receives his instruction. This method naturally requires that the teacher and building be kept as cleanly as the surgeon and his operating-room. The first lesson taught the student in the clinic before operating on patients should be to place his own mouth in an hygienic condition as well as the patient's.

Most teachers discourse on diseases of the gums and alveolar process as pyorrhea alveolaris. It is an impossibility to teach students the pathology of these tissues under such a name After the student learns what the term means he is all at sea when the different stages of inflammation are met with. He must always look for pus and if no pus is present, there can be no "itis." I do not care whether the disease is called interstitial gingivitis or alveolitis; both are good terms. The term pyorrhea alveolaris should be used when pus is present. Few teachers on orthodontia give an intelligent course on etiology of deformities of the jaws and irregularities of the teeth. Another great mistake of some teachers is the invention of a new pathology to fit some particular mechanical hobby to advertise themselves. What is needed in dental schools is a better educated class of teachers to give a broader course.

Dr. M. H. Fletcher, Cincinnati: We are not all blessed with patients who can or will pay for services rendered by a physician or highly skilled stomatologist to treat diseases of the mouth. What are these people to do? Let us put ourselves in the position of some poor fellow who has no money to pay except for extraction and for a set of store teeth when the natural teeth are all gone. I have for years been an advocate of advertising dental offices, provided they have men to do this kind of work properly. Were we to have none but the highly educated practitioners, the probabilities are that many people would have to go without treatment and become toothless; or else men capable of more successful careers than those promised here, would necessarily deteriorate into that kind of practice at a very small price. On the other hand, there is a large clientele requiring what most of us can not give—treatment from the most highly skilled men that can be had, trained in anatomy, histology, pathology and diagnosis. I am thoroughly in accord with Dr. Talbot as to the failure in most of our dental colleges to teach pathology adequately in preparation for the practice of stomatology. Nomenclature is a point which has caused me a great deal of chagrin at times. Medical men say, for example, "You do not have in the text-books any description of the disease known as pyorrhea alveolaris." I would advocate every method that can be adopted to increase the knowledge of our students in the line of pathology and the treatment of disease.

Dr. M. L. Rhein, New York: I agree with Dr. Talbot as to the necessity for a generally better education, both of the teacher and student. Until we reach the same educational plane that practitioners in general medicine must attain, it is absurd for dentists generally to speak of dentistry as being on an equal footing with general medicine.

The subject of the teaching of pathology is one on which I feel very strongly. It is almost impossible to teach pathology of a part of the body until the student has not only had proper instruction in, but has shown by his examinations a proper understanding of, general pathology.

Dr. N. S. Hoff, Ann Arbor, Mich.: The teaching of the subject of pathology is difficult, and I do not think it all depends on the extent of the student's preliminary education, neither does it depend altogether on the education of the teacher. Sometimes a student who is not what we call well educated gains a good understanding of pathology. On the other hand, a student with the very best recommendations, may disappoint us by turning out to be an inferior student. I hesitate to criticize the attitude that the dental colleges have taken towards the matter of preliminary education.

Vida A. Latham, Chicago: Pathology comes a little too early in the present course of instruction. Pathology presupposes and accepts a knowledge of everything gone before; it takes in physiology, anatomy, general medicine, general pathology, surgery, etc. When we get it in the first and second years, as we do in many schools, it is difficult for a teacher of pathology to get the student to understand and make the references to all classes of work. A teacher gives a few points to learn by heart, and as a rule the student is not required to learn anything outside of that. I think the system of teaching in Michigan University some years ago, which required the student to look up branch or essay subjects, was one of the best incentives to a student to obtain a broader education in dentistry.

The literature of pathology, written by medical men as a rule, unfortunately, does not apply to conditions of the mouth particularly, as the tumors and pathologic conditions of the mucous membrane, the salivary glands, lymphatics of the mouth, etc., are not sufficiently known. I doubt if any one knows whether or not we have lymphatics of the teeth. Why do not we make investigations along that line? The illustrations that are seen in the dental museums are usually of the gross anatomy. Where is the work done that would be acceptable, like Professor Shambaugh's work on the internal anatomy of the ear, the lymph spaces? We have no such work. The work of Dr. Broomell, of Philadelpia, is noted as of the best, though he is only a beginner in the subject, and he is perhaps the only man that has done the work in this country. But Dr. Broomell gets little credit for it—where do you hear him quoted? Where are other men who have tried to give us some dental pathology, dental bacteriology, dental histology? With the exception of Dr. Miller, not one has had an incentive to carry the work through. It is persecution to have to work night and day to earn bread and butter that research may be carried on! For that reason scientific dentistry and scientific medicine are the losers. I know laboratory men most eminent in this country and abroad. Have most of them ever received any credit or scientific standing for what they have done? The universities seldom recognize their work; the profession as a whole does not recognize it or seems to think anything but mechanics needed; and we are brought back to the same question: Why should we have professional dentistry taught by ordinary medical men? I think that this Section should make an effort to encourage the carrying on of research and secure laboratory facilities. The Section on Surgery invites men from abroad as guests. Why should not we? Why do we not invite Zigmundy, von Ebner, Zuckerkandl, Walkhoff and Gysi to attend our meetings? Then our meetings would be more largely attended. What we need is scientific dentistry and pathology.

Dr. F. B. Moorehead, Chicago: Three years is altogether too short a time in which to teach pathology. The didactic work given in two brief terms in dental colleges is altogether inadequate so far as the marvelous study of pathology is concerned. That course is not now long enough in the medical curriculum, and it will never be long enough in the dental school. I myself have spent several years in the study of pathology since graduation, and I am not yet inside the portals of the study of pathology.

In my opinion the subject of pathology ought not to be left to the department of pathology alone; other departments should be competent to teach it also. Students should be clinically taught practical pathology in the oral surgery clinic by a man who knows pathology. In that clinic every piece of tissue removed from the human mouth should be subjected by the students of the senior class to microscopic examination and study so that they may get a practical application. No matter how perfect one's preparation, no one can properly teach pathology didactically. It is not a didactic, but purely a laboratory subject. Therefore, we must have laboratories for the teaching of pathology, which presupposes that the student has done the required amount of work in histology. I have shown sections of tissue to senior students who were unable to determine whether a certain section was heart muscle—striated muscle—or connective tissue. A student who does not know normal histology can not intelligently study pathology. He must know normal tissue before he can study abnormal tissue. The student must first have a thorough course in histology, and then must be taught pathology practically. After this the student will be in a position to study the subject intelligently. The most we can hope for, is to prepare the student, in the three years he is with us, to take up the subject as a postgraduate study.

Dr. G. V. I. Brown, Milwaukee: Every one who teaches oral pathology will, I think, agree that there are four difficulties that must be met. First, insufficient time. I was an ardent advocate of the four-year course, and am glad to hear the general sentiment expressed in favor of it to-day. The second difficulty, and a very serious one, is that there is no literature on which any one who undertakes to give a modern course in pathology of the mouth, teeth, jaws, etc., can depend. To frame a course of lectures such as might satisfy one's own idea of what they ought to be if they are to be beneficial to the students, requires a great deal of general work. More books and miscellaneous literature must be consulted than it is really fair to ask students to undertake to go over in following that course of lectures. I meet this difficulty in my work at the University of Iowa as well as I can by preparing at the end of each year a long list of questions covering as far as possible those principles which I consider to be the most essential. I try to prepare them in such manner that the student can find the answers in no one work. This, in a general way, requires him to do more or less collateral reading in order to prepare answers, and it is on those questions that examination in the subject is based. The third and worst difficulty is that there is a lack of proper sentiment behind the study.

The fourth difficulty troubles me the most, and that is this teaching of applied pathology. In the University of Iowa, with which I am connected, the students have a thorough course in histology followed by laboratory and didactic work in general pathology before they come to me. I have put my work in two divisions: First, what I call the dental division or oral pathology, in which I teach only pathology of diseases of the teeth and surrounding tissues, the treatment of which does not belong to my course; and, second, that part of oral pathology properly belonging to the course in oral surgery, and of which I teach the treatment. I take up the consideration of the pathology in the following order: Etiology, pathology, symptoms, diagnosis, prognosis, and treatment of each disease, thus making the subject practical. The weakest point in all our teaching is due to the variance among those who should have opinions on the subject, more in accord.

Dr. L. G. Noel: I am indebted to those teachers who prepared letters giving their views in the matter of teaching pathology. I gathered from these letters that pathology is being taught in most of our dental schools, not from one chair alone, but from several, so that there is no escape from the subject. If a man is studious he can not help absorbing a large amount of pathologic knowledge while being instructed in the bacteriologic and histologic departments, and he is also being thoroughly taught pathology from the chair of surgery in nearly all dental schools as well as in the clinical course. It is impossible for the student to have too much pathologic teaching. I believe that all dental students should be graduates in medicine before the dental school. We should then have all the branches that the student had studied in medical school, applied to his specialty of dentistry.

DEMENTIA PRÆCOX.

A COMPOSITE HISTORY OF TWO HUNDRED CASES WITH BLOOD FINDINGS IN FIFTY CASES.

H. D. PURDUM, M.D., AND R. E. WELLS, M.D.
Assistant Physician in Northern Michigan Asylum.
TRAVERSE CITY, MICH.

Several articles devoted to the etiology of dementia præcox have appeared within the last year in English and American journals; still, additions and contributions to knowledge on this point are much to be desired. It is with the hope of adding, even though slightly, to the knowledge of this condition that we present the following clinical findings:

On examining the histories of 200 cases, in 65 per cent. we were able to find some mental or nervous defect in the family. The greater majority of these patients were apparently normal in body and mentally well endowed; in fact, a great many showed unusual ability to acquire school knowledge until the pubescent period was reached. At this time many complained of nervousness and loss of ambition; others were shy, seclusive and showed vasomotor irritability; again others developed exaggerated sexual feelings and practiced masturbation.

These symptoms usually passed almost unnoticed by the other members of the family for a year or two; then the majority of these patients became restless, complained of dull frontal headache, vivid disagreeable dreams, anorexia, digestive disturbances and inability to obtain restful sleep. If seen by a physician at this time they were usually found to have exaggerated deep and superficial reflexes, vasomotor disturbances (such as cold, clammy hands, cyanotic feet, dermatographia), anemia and loss of weight. To the prodromal symptoms just enumerated were now added the first real signs of mental aberration or the true onset of the psychosis. The first psychic field to show definite perversions was the emotional, and this was demonstrated in the change of feeling toward home, relatives and friends, and by periods of weeping, silly laughter and phobias. The next field to suffer included the various special senses. The patients heard unnatural sounds and voices, saw queer objects and visions, smelled disagreeable odors, their food tasted unnatural, sexual feelings were heightened or perverted, and frequently at night they experienced sensations as if suspended in space or lowered into some deep cavern. The patients as a rule at this stage of the psychosis tried to explain to themselves the cause of these unusual sensations, and as their judgment was defective, delusional ideas were the result. Delusions of persecution appeared first, and on them were engrafted those of position, grandeur, importance, religion, poisoning and also those of a sexual nature. At this point in the progress of the mental disease the attitude, manner and will became affected. Under the influence of hallucinations and delusions the patients usually became irritable, suspicious and egotistic. Lack of ambition and inability to perform simple tasks were quite noticeable at this time. Impulsive acts were often seen, some patients setting fire to their homes or destroying property while under the influence of these imperative ideas. A tendency to wander and travel was observed in a great many of these cases. As Kraepelin states, there is no doubt that among tramps a large percentage suffers from an arrested form of this disease.

The various psychic anomalies just enumerated were found to be more or less common to all cases of dementia præcox studied, but at this point in the progress of the mental disease certain psychic fields showed greater anomalies than others. For instance, in one group of cases the volitional field was found to be the one principally affected, the other symptoms being more or less in the background. In another group the emotional field was the one that suffered most, and in still another group the judgment showed the greatest weakness. For the above reasons the various authorities on psychiatry have divided dementia præcox into the catatonic, hebephrenic and paranoid forms. The three above-mentioned forms had, in the cases which we studied, a great many symptoms in common, but the degree to which certain psychic fields were invaded by the disease made these types stand out almost as distinct types of disease.

The most prominent symptoms displayed by the catatonic patients were those pertaining to anomalies of the volition or will, such as stupor with mutism, negativism, and more or less constant hypermuscular tension or excitement, during which the patients were destructive, untidy and noisy by shouting, and demonstrated stereotypy of speech and movements. While in the stuporous state the patients required a great deal of attention, were exceedingly difficult to care for, and usually needed to be fed artificially. The change from the stuporous to the excited state was frequently found to occur and usually took place spontaneously. One patient who had been stuporous for over three months suddenly became excited, got out of bed, forced his face through a large pane of glass and succeeded in dissecting the greater part of the flesh from the facial bones. After the wounds were dressed he again became stuporous and is in that condition at the present time, over two years since the above attack. The periods of excitement in these cases were usually of short duration, lasting as a rule from the few seconds consumed by one impulsive act to three or four days. We found a great many of these patients in a mixed state, that is, in a condition of stupor and mutism with rhythmic movements and some constraint. Delusions, illusions and hallucinations in these cases, though present as a rule, were not prominent. Some authorities claim that all of the volitional anomalies are prompted by delusional ideas, but we were unable to prove this except in a few cases. The prognosis was found to be far better in this particular form than in the other two forms of the disease. Twenty-two per cent. were able to return to their homes; of these 10 per cent. had recovered and 12 per cent. were slightly demented. A few of the slightly demented patients were readmitted to the institution later.

In the hebephrenic form the emotional field presented the principal characteristic anomalies. The ones most frequently found were general apathy, unprovoked silly laughter, lack of interest shown on meeting friends or relatives, frequent blushing, weeping, shyness, seclusiveness and preoccupied states. As in the catatonic form, delusions and hallucinations were usually present, but of minor importance when compared with the emotional phenomena. The mental decline in these cases was uniformly progressive, with a few remissions and a small percentage of recoveries. Most authorities claim that the hebephrenic form of dementia præcox goes to make up about 75 per cent. of the tramps and vagabonds.

The paranoid form, on the other hand, showed marked irregularities in the field of judgment. The most striking features were the delusional ideas and the formation of more or less fixed delusions. The delusions in reference to persecution were the first to appear, on which were engrafted those of grandeur, position, power, religion and occasionally those of an erotic nature. This type of the disease usually affected the patients later in life than the other two forms. On account of these delusional ideas being partly based on facts, patients of this type often came to the asylum for the first time as late as the thirty-fifth year of age, after having served several short terms in prison or having caused their relatives an enormous amount of trouble and anxiety. Authorities on criminology and psychiatry have found that a large percentage of eccentrics, anarchists and criminals is made up of sufferers from this form of dementia præcox. On account of their apparently more or less logical ideas the civil courts often find them guilty of some criminal offense or let them go free, exempt from the guardianship of an institution for the insane, until the psychosis is well advanced. No remissions or recoveries occurred in the few cases of this form included in this paper.

Tables 1 and 2 contain the blood findings in twenty-five cases of catatonic stupor and twenty-five cases of hebephrenia. Nine of the catatonic cases showed some slight mental impairment, but the entire hebephrenic group is composed of fairly recent cases. Wright's blood stain was used for the differential count and Erlanger's sphygmomanometer for the blood pressure.

Patient 11 was operated on in January of this year and four-fifths of the right lobe of the thyroid gland was removed. For six months previous to the operation he had been mute, rigid, tube-fed and cared for in bed. Immediately following the operation he became mentally clear and talked freely. This hopeful condition lasted five days, when the patient's mind became clouded and convulsive movements were seen to involve the angles of the mouth and the extremities. On the seventh day the patient had four tetanic convulsions lasting from three to four minutes each, during which the trunk and extremities were in a state of extreme flexion. We were of the opinion that the parathyroid glands of the right side had been either removed or injured during the operation and the tetanic convulsions were the result. Five-grain tablets of thyroid extract were administered every four hours. After the first dose, the patient had no more convulsions, and when four tablets had been given, the drug was discontinued. During the following six weeks the patient was cared for in bed, being very destructive, delusional and negativistic. At the end of this time he began to improve and was allowed to get up and dress. Improvement has been gradual since, and at present the patient is mentally clear, takes considerable interest in his surroundings and occupies his time by reading and assisting the attendants with the ward work. Delusions and hallucinations are absent and the patient appears to be in a normal state, except that his movements as well as his thought processes are slow. Since the operation he has gained 23 pounds and his blood-findings are practically normal, aside from a mild leucocytosis and a low erythrocyte count.

After the tabulated blood examinations were made in cases 23 and 33, thyreoidectin was administered in five-grain doses every eighth hour for one week. A second blood count was made at the end of this period and the following changes noted: In case 23, the eosinophile percentage increased from 6 to 14.2 and the total leucocyte count from 6.592 to 8,884, while the neutrophile percentage decreased from 61.4 to 49.6. In case 33, the eosinophile percentage increased from 15.4 to 25.1 and the total leucocyte count from 10,660 to 14.340, while the neutrophile percentage decreased from 61.7 to 45.6.

Bazzicalupo's theory that the eosinophiles and neutrophiles that have undergone presenile changes is well illustrated in the table. Those cases that showed an unusually high eosinophile count also showed a correspondingly low neutrophile percentage.

The urine of forty-four out of the fifty cases tabulated showed an excess of indican.

While we do not feel justified in making deductions from the above findings, yet we consider the prevailing mild leucocytosis and the increase in the percentage of the eosinophile and large mononuclear cells with a low neutrophile count of considerable interest. The above facts just enumerated in reference to the blood and urine point strongly toward a physical basis for this disease, possibly an autointoxication of intestinal or glandular origin.

Pneumococcus Nephritis.—Ferrand diagnosed acute nephritis in a child of 6, previously healthy. The child died in three days, and the trouble proved to be a *pneumococcus* infection with multiple localizations, most severe in the kidneys. The lesions in the pleuræ and lungs were subordinate. Papillon had a similar case in his service, the signs of the acute nephritis dominating the clinical picture although there was pneumonia of the right lung, evidently the primary affection. The meninges were also involved. The case was still under observation when reported in the *Bulletin de la Société de Pédiatrie*, April, 1908

PSYCHOTHERAPY.*

M. A. BLISS, M.D.
ST. LOUIS.

The idea I desire to present is, that, as far as psychic influences are to be curative, they must be applied with that end solely in view and not with a reservation that admits greater development of a neurosis, so that the observer may make an interesting psychic analysis, may keenly dissect and examine in cool, critical fashion the abnormal working of the mind machinery as the physiologist examines the beating heart of the dog—good for science but bad for the dog. It goes without saying that we should apply our very best efforts to comprehend the innermost recesses of the patient's consciousness, but if in our warm pursuit of psychologic data we lose sight of our ultimate aim—the welfare of the patient—so much the better perhaps for scientific study, so much the worse for the patient. There is a very close comparison between this tendency in neurology and the overzealousness in surgery, where a desire to build up statistics, to do rare and unusual operations, to witness in perhaps a purely scientific spirit the progress of disease processes may contribute ultimately to the welfare of mankind at large, but works hardship on the individual sufferers. The analogy will apply probably in all fields of the healing art, but certainly not least in the application to psychic work.

In spite of the effort to reduce psychotherapy to a scientific basis must we not after all confess that it is an art and must be applied as an individual and personal quality? Can it anywhere be claimed that the art may be mastered equally by men of equal ability any more than all men of equal intelligence and industry might paint equally acceptable pictures or write literary productions? I think not. Moreover, the great bulk of the work in this field must be generously interspersed with kindliness and genuine human sympathy, with a spirit of friendship and comradeship, if it is to give the best results. The good old family doctor of the days now disappearing, who acted as general family counselor in moral as well as physical vicissitudes, has very successfully filled the rôle of psychotherapist. His very presence brought about favorable results that cold scientific analysis would utterly fail to attain.

Very recently one of my best friends in neurology, whose scientific work is well and most favorably known, was reporting a study of a hysteric situation. He was asked what suggestive work had been done toward removal of symptoms. He very naively replied, "None. In fact, it was the spirit of the game not to disturb the development of hysteric symptoms, but the hope existed that more profound manifestations might arise, that more might be learned of their nature." It may prove disconcerting in the end to find that a dislodgment of well-intrenched ideas is entirely beyond his suggestive powers.

It does not seem far-fetched to compare the development of psychic deviations to those of a purely physical nature. The relative ease of removal is certainly present in the beginning. So we may not privilege ourselves to study the growth of a neurosis coolly; we must apply our best efforts to its cure and store away whatever we may learn of scientific value, the acquisition of which does not interfere at all with the best interests of the sufferer.

Another phase of this subject and one which gives rise to wide differences of opinion is how far may we use placebos and other means of presumably pure suggestive nature like the static battery, as a quick and easy way of removing troublesome symptoms which may arise in the progress of any neurosis.

There is good reason for believing this rarely justifiable, and certainly the tendency is toward less careful and painstaking efforts to get the patient to realize the mental origin and method of management of his troubles. One might compare this to the use of the coal tar products for the relief of headache. A symptom is relieved, but the underlying cause is in no wise removed or affected except possibly for the worse. Most psychics are indefatigable in their search for medicinal remedies and come to offices ladened with thirty or forty prescriptions, about half of which call for one or another of the bromid salts. It may require an hour or more of valuable time and all our persuasive eloquence to put the truth plainly before them. We may not succeed even then, but it is none the less our duty to advise against all drugs, currents, etc., when the cause is a mental or moral one, than it is to write a prescription for quinin when the plasmodia appear in the blood.

I have had patients, with whom I had labored diligently, settle themselves rebelliously in a chair and declare they were not going to leave until they got a prescription for some medicine. They were tired trying my methods which, however successful at times, at other times failed completely to give relief. How easy to write for a cochineal mixture for such a patient to build up an elaborate expectancy and perhaps be later assured by him that it "worked like a charm." If there is a field in which psychotherapy actually cures anything, and it is the firm belief of many, if not most, neurologists that there is, there can be no excuse for weakly succumbing to this temptation to do at times what the quack does all the time, i. e., give some innocuous stuff to satisfy a desire of the patient and let Nature and hopeful expectancy do the rest.

Psychic analysis after the method of Freud and Jung certainly contributes extremely valuable knowledge to our branch of study, but it is questionable whether the material used in these experiments is not in some measure at least sacrificed to scientific enthusiasm.

After all, the largest use we find for psychotherapy, not the most urgent and indispensable but the most frequent, is in simple nervousness arising in patients who have never learned not to be governed by their emotions, whose philosophy has never been developed. When we run on to a genuine neurasthenia or psychasthenia, it takes two, three or four years to get it well, psychotherapy or none. A deep-seated hysteria we do not cure, though we fondly pride ourselves in our ability to "modify the personality." Our influence on the genuine psychoses, when we have crossed the shadowy line dividing them from simple nervousness, does not swell us with pride. It depends in a large measure on our ingenuity in devising employment, environment, and wholesome ways of living whether we succeed or not. The fascination of laboratory experiment and the easy way of the placebo may appeal to us according to our mood, but neither should be allowed to overweigh the one legitimate aim of our efforts—the cure, partial or complete, of the patient.

Clinical Notes

SUDDEN COLLAPSE FOLLOWING INJECTION OF DIPHTHERIA ANTITOXIN; RECOVERY.

FRANK W. THOMAS, M.D.
CLAREMONT, CAL.

Recent reports in The Journal of fatal results following the use of antitoxin, especially the cases reported by Drs. Wiley[1] and Boone,[2] prompt me to report a very unpleasant experience with serum a few months ago. Although the patient survived, I certainly do not care to have any more experience of like character.

Dec. 15, 1907, I was called to see a boy 15 years of age. He had always been healthy in every way, until the past few days, when he thought he had taken cold, and was now complaining of his throat. Examination showed a flushed face, rapid respiration, and quick pulse, 120 per minute. He breathed through the open mouth, indicating nasal obstruction. Inspection revealed a large mass of diphtheritic membrane which almost filled the pharyngeal and postnasal spaces. I at once sent for antitoxin, and on its arrival injected, by the usual technic, a dose of 4,000 units into the subscapular region.

Immediately there was a change in the boy's countenance. A look of intense anxiety came over him, and the lips, face and neck quickly became livid in appearance. He gasped for breath, and cried out that he was smothering, and that he had a pain in his heart. Froth poured from his mouth, and he clutched with his fingers at his throat and chest. There was a peculiar death-like stare in his eyes; the pupils became widely dilated, and very soon he went into convulsions, throwing himself from one side of the bed to the other. Finally his breath seemed to leave him, and he dropped back on the bed in a state of complete collapse and unconsciousness, while the radial pulse entirely disappeared from both wrists. Death seemed imminent.

Restorative measures were promptly instituted in the form of strychnin, atropin, and nitroglycerin, hypodermically, while heat was applied to the extremities and hot coffee injected into the bowel. Dr. Frank Garcelon of Pomona was called in consultation. Stimulation was pushed to the limit, without any apparent benefit, so far as restoration of consciousness or pulse was concerned. After lying in this condition for an hour and a half with no improvement, and as the throat was filling up rapidly with the false membrane which continually threatened strangulation, it was decided to try another dose of antitoxin, and 3,000 units were injected in the submammary region. One hour later, another dose of 2,000 units was administered. In each instance strychnin 1/30 gr. was given hypodermically coincident with the antitoxin.

No immediate effect was noticeable from either of these doses, one way or the other. Respiration continued weak and rapid, while the extremities were cold and blue. The case at this time seemed hopeless. One hour later an ounce of hot saturated camphorated oil was injected into the bowel, and retained. Two hours later respiration began to improve, and a faint radial pulse could be detected, the first perceptible in six hours' time, and the patient soon regained consciousness, but was very much prostrated.

As the boy could not now swallow, alcoholic stimulants were freely given, and peroxid of hydrogen spray, full strength, was used in the nose and throat at frequent intervals. At 9 a. m., the next day, 3,000 units of antitoxin were given, and the same sized dose repeated at 1:30 and 5:30 p. m., making in all 18,000 units administered in twenty-two hours.

Improvement in pulse and respiration became more noticeable, and the symptoms much more favorable, but the membrane did not begin to slough until the fourth day. After this it was freely cast off. On the eighth day severe muscular and articular pains came on, and the characteristic eruption appeared over the whole body, accompanied with intense itching, and the eyes became bloodshot.

Absolute rest was enjoined for several weeks after all troublesome symptoms had disappeared, and strychnin was continued until the patient had regained his strength. Convalescence was rather slow, but the patient finally made a complete recovery.

The question may be asked why succeeding doses of antitoxin were given this patient after the untoward effect of the first dose. The answer is that the boy's system was so thoroughly saturated with the toxemia of the disease that recovery seemed impossible without heroic measures such as antitoxin offers. The precaution was taken to give strychnin coincident with each of the succeeding doses of antitoxin for the purpose of sustaining the flagging heart action. Whatever theory may be applied to the case, the important thing is that the boy recovered. Without vigorous and continued stimulation death would certainly have followed.

The question of the untoward effects of serum injections have attracted the attention of the profession to a considerable extent within the past few months,[3] and now the federal government, through the Marine-Hospital Service, is making extensive investigation and study of the subject with reference to this point, and it is hoped that the department will be able to throw light on a mysterious condition concerning which we are in the dark at the present time.

The difficulty is that we have no criterion by which we may be able to foresee contraindications for the use of the serum that is so universally recognized as the most potent remedy we have with which to combat the poison of diphtheria. I have used antitoxin for years, and have given it twenty-five times since that unfortunate experience five months ago, and only with good results; but in the light of the experience reported during the past few months it behooves the profession to be on guard in the use of this remedy that we have heretofore given with feelings of absolute safety.

A NEW METHOD FOR THE QUANTITATIVE ESTIMATION OF ALBUMIN IN URINE.

PRELIMINARY REPORT.*

EDWARD H. GOODMAN, M.D.
Physician to the Dispensary of the Phipps Institute for the Study, Treatment and Prevention of Tuberculosis; Dispensary Physician to the Presbyterian Hospital; Assistant Instructor in Medicine, University of Pennsylvania, etc.

AND

SUZANNE STERN.
PHILADELPHIA.

Although there have been many new methods devised in past years which have simplified and enriched our laboratory equipment, there seems to have been no method suggested whereby the percentage of albumin in a given specimen of urine can be rapidly determined. The only means we possess is the Esbach albuminometer, which besides being inaccurate, possesses the added disadvantage of requiring twenty-four hours before a result can be obtained.

We have worked out a method which is extremely simple, accurate and which gives results in a few minutes. It is based on the precipitation of albumin by phos-

* A preliminary report from the private laboratory of Dr. John H. Musser.

phosphotungstic acid in the presence of a mineral acid. We dissolved 1 gm. of crystallized egg albumin in 100 c.c. of distilled water (Solution A). Of this we took 1 c.c. and diluted with 9 c.c. of distilled water (Solution B) so that in the 10 c.c. there was 0.01 gram of albumin; in 1 c.c., 0.001 gram, and in 0.1 c.c. 0.0001 gram. We put in a test tube 5 c.c. of the following solution:

Phosphotungstic acid	1.5 gm.
Hydrochloric acid (conc.)	5 c.c.
Alcohol 95 per cent., q. s. ad..............	100 c.c.

We found that if the above solution of egg albumin (Solution B) were added with a pipette graduated in 0.1 c.c. that it took 0.1 c.c. to cause a cloudy precipitate with the phosphotungstic acid; in other words, there were 0.0001 gram albumin in the 0.1 c.c. of the albumin solution.

To prove the delicacy of this we took 1 c.c. of Solution B and diluted it with 9 c.c. of distilled water so that in the 10 c.c. there was 0.001 gm. albumin, in 1 c.c., 0.0001 gm., and in 0.1 c.c. 0.00001 gm., and we found that it required exactly 1 c.c. to cause a precipitate, or 0.0001 gram albumin.

Having established the delicacy of the test we applied our method to urine. First the Heller's test was made and if much albumin was present, the urine was diluted 1 in 10, if not, undiluted urine was used. Of the phosphotungstic acid solution, 5 c.c. were put in a test tube and then with a 2 c.c. pipette graduated in tenths of a c.c. the filtered urine was added to this, shaking after the addition of each tenth, and adding urine until a whitish cloud appeared. The number of tenths of a c.c. was read off and expressed in terms of 100 c.c.

For example, if it took 1 c.c. of diluted (1 to 10) urine, there was .0001 gram albumin in .1 c.c. of undiluted urine, or in 100 c.c. there was 0.1 gram albumin, or 1 gram in 1000 c.c. On the other hand, if 0.7 c.c. diluted urine were used, then 0.07 c.c. undiluted urine equals 0.0001 gm. albumin; 7.0 c.c. equals 0.01 gm. albumin and 700 c.c. equals 1.0 gm. albumin. The following equation gives the percentage:

As 700 : 1.0 :: 100 : x or 0.142 per cent. or 1.42 per thousand.

Our findings have been controlled by the gravimetric method and the results are given below:

No. 1.—Titration method...0.06	per cent., or 0.6	pro mille
Gravimetric method.0.06	per cent., or 0.6	pro mille
No. 2.—Titration method...0.166	per cent., or 1.66	pro mille
Gravimetric method.0.1100	per cent., or 1.10	pro mille
No. 3.—Titration method...0.05	per cent., or 0.5	pro mille
Gravimetric method.0.05	per cent., or 0.5	pro mille
No. 4.—Titration method...0.33	per cent., or 3.3	pro mille
Gravimetric method.0.34	per cent., or 3.4	pro mille
No. 5.—Titration method...0.12	per cent., or 1.2	pro mille
Gravimetric method.0.10	per cent., or 1.0	pro mille
No. 6.—Titration method...0.1	per cent., or 1.0	pro mille
Gravimetric method.0.17	per cent., or 1.7	pro mille

The method, as is seen, is exact, sensitive, simple and possesses the great advantage of giving the amount of albumin in a specimen of urine in a very few minutes. Further work is being carried on to determine the errors, if any, in this procedure, and a future paper will contain our final conclusions as to the value of our method.

Children's Hospital, Hobart, Tasmania.—The committee appointed to judge the designs for the proposed children's hospital have recommended that Mr. Rudolph Koch be awarded the first prize. The design provides for 24 beds, two wards of 10 beds, one of 3, and an isolation ward containing 1 bed.

CORN OIL IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

JOHN RITTER, M.D.
Instructor in Medicine, Rush Medical College.
CHICAGO.

The medical profession is fully conversant with the fact that, in the treatment of pulmonary tuberculosis, the oils and fats take foremost rank. All tissue waste, in excess of that in health, which always takes place during the active tuberculous process, must be met by an abundance of aliment to restore the metabolic equilibrium. Our chief reliance usually is placed on the ingestion of easily assimilable and readily digestible food. As food values the fats and oils are of the most importance. If the tuberculous patient refuses to take, or does not well tolerate, fats and oils which form part of the daily diet, such as butter, yolk of eggs, bacon, etc., then recourse must be had to some animal or vegetable fat given as a medicine.

Of animal oils, that obtained from the liver of the cod fish has for years been given the preference. Of late, the use of olive oil has come greatly into favor. Both cod liver oil and olive oil are expensive, and the price of these oils is, as a rule, beyond the reach of most tuberculous patients, as most patients suffering from pulmonary tuberculosis belong to the poorer classes. This has induced me to look about for an oil or fat which possesses all the good qualities and properties of either cod liver oil or olive oil, or of any other good vegetable oil, and which is inexpensive, palpatable, easily assimilated, well borne by the stomach and does not cause nauseous eructations. My attention was directed about a year ago to an oil obtained from corn or maize and I began to recommend and prescribe it to patients who applied at the Central Free Dispensary of Chicago and who were suffering from pulmonary tuberculosis. This was to be used in lieu of either cod liver oil or olive oil. From the fact of its inexpensiveness, it being about one-fourth the price of that of any other oil or fat usually prescribed in pulmonary disease, I wished to give corn oil a fair trial. I ascertained from reliable sources that the output of corn or maize oil is practically unlimited and it being only a by-product in the manufacture of starch minimizes its cost of production and makes the selling price proportionately low. The low price of maize oil, combined with all the good qualities of a palatable and wholesome oil, makes it the ideal oil for patients suffering from pulmonary tuberculosis.

I have given it not only to such as applied at the Central Free Dispensary for treatment, but also to such as came under my care at the Tuberculosis Institute and in all cases with equal gratifying result. I am convinced, from many close observations, that as a food or tissue builder it is fully equal to cod liver oil or olive oil. The ingestion of corn oil is well tolerated. It does not cause the nauseous eructations which usually follow the taking of cod liver oil, and the prolonged and increasing dosage is always well borne by the stomach.

Corn or maize oil (oleum mayidis, oleum zea mais) is obtained from ordinary corn. The amount of oil in corn varies from 3.5 to 6 per cent. The oil is found almost entirely in the germ which represents about 6.5 per cent. of the weight of the corn and about 50 per cent. of this germ is pure oil. It possesses all the properites of the fixed oils, being insoluble in alcohol or water, but very readily soluble in chloroform, ether or carbon bisulphid. Its color is light straw, it possesses

A NEW METHOD FOR THE QUANTITATIVE ESTIMATION OF ALBUMIN IN URINE.

PRELIMINARY REPORT*

EDWARD H. GOODMAN, M.D.
Physician to the Dispensary of the Phipps Institute for the Study,
Treatment and Prevention of Tuberculosis; Dispensary
Physician to the Presbyterian Hospital; Assistant
Instructor in Medicine, University of Penn-
sylvania, etc.

AND

SUZANNE STERN
PHILADELPHIA

Although there have been many new methods devised in past years which have simplified and enriched our laboratory equipment, there seems to have been no method suggested whereby the percentage of albumin in a given specimen of urine can be rapidly determined. The only means we possess is the Esbach albuminometer, which besides being inaccurate, possesses the added disadvantage of requiring twenty-four hours before a result can be obtained.

We have worked out a method which is extremely simple, accurate and which gives results in a few minutes. It is based on the precipitation of albumin by phosphotungstic acid in the presence of a mineral acid. We dissolved 1 gm. of crystallized egg albumin in 100 c.c. of distilled water (Solution A). Of this we took 1 c.c. and diluted with 9 c.c. of distilled water (Solution B) so that in the 10 c.c. there was 0.01 gram of albumin; in 1 c.c., 0.001 gram, and in 0.1 c.c. 0.0001 gram. We put in a test tube 5 c.c. of the following solution:

---

[1] THE JOURNAL A. M. A., Jan. 11, 1908, 127.
[2] THE JOURNAL A. M. A., Feb. 8, 1908, 475.
[3] THE JOURNAL A. M. A., March 14, 1908, 875.
[*] A preliminary report from the private laboratory of Dr. John H. Musser.

Phosphotungstic acid	1.5 gm.
Hydrochloric acid (conc.)	5 c.c.
Alcohol 95 per cent., q. s. ad	100 c.c.

We found that if the above solution of egg albumin (Solution B) were added with a pipette graduated in 0.1 c.c. that it took 0.1 c.c. to cause a cloudy precipitate with the phosphotungstic acid; in other words, there were 0.0001 gram albumin in the 0.1 c.c. of the albumin solution.

To prove the delicacy of this we took 1 c.c. of Solution B and diluted it with 9 c.c. of distilled water so that in the 10 c.c. there was 0.001 gm. albumin, in 1 c.c., 0.0001 gm., and in 0.1 c.c. 0.00001 gm., and we found that it required exactly 1 c.c. to cause a precipitate, or 0.0001 gram albumin.

Having established the delicacy of the test we applied our method to urine. First the Heller's test was made and if much albumin was present, the urine was diluted 1 in 10, if not, undiluted urine was used. Of the phosphotungstic acid solution, 5 c.c. were put in a test tube and then with a 2 c.c. pipette graduated in tenths of a c.c. the filtered urine was added to this, shaking after the addition of each tenth, and adding urine until a whitish cloud appeared. The number of tenths of a c.c. was read off and expressed in terms of 100 c.c.

For example, if it took 1 c.c. of diluted (1 to 10) urine, there was .0001 gram albumin in .1 c.c. of undiluted urine, or in 100 c.c. there was 0.1 gram albumin, or 1 gram in 1000 c.c. On the other hand, if 0.7 c.c. diluted urine were used, then 0.07 c.c. undiluted urine equals 0.0001 gm. albumin; 7.0 c.c. equals 0.01 gm. albumin and 700 c.c. equals 1.0 gm. albumin. The following equation gives the percentage:

As 700 : 1.0 :: 100 : x or 0.142 per cent. or 1.42 per thousand.

Our findings have been controlled by the gravimetric method and the results are given below:

No. 1.—	Titration method...	0.06	per cent., or 0.6	pro mille
	Gravimetric method.	0.06	per cent., or 0.6	pro mille
No. 2.—	Titration method...	0.166	per cent., or 1.66	pro mille
	Gravimetric method.	0.1100	per cent., or 1.10	pro mille
No. 3.—	Titration method...	0.05	per cent., or 0.5	pro mille
	Gravimetric method.	0.05	per cent., or 0.5	pro mille

	Gravimetric method.	0.34	per cent., or 3.4	pro mille
No. 5.—	Titration method...	0.12	per cent., or 1.2	pro mille
	Gravimetric method.	0.10	per cent., or 1.0	pro mille
No. 6.—	Titration method...	0.1	per cent., or 1.0	pro mille
	Gravimetric method.	0.17	per cent., or 1.7	pro mille

The method, as is seen, is exact, sensitive, simple and possesses the great advantage of giving the amount of albumin in a specimen of urine in a very few minutes. Further work is being carried on to determine the errors, if any, in this procedure, and a future paper will contain our final conclusions as to the value of our method.

2035 Chestnut Street.

Children's Hospital, Hobart, Tasmania.—The committee appointed to judge the designs for the proposed children's hospital have recommended that Mr. Rudolph Koch be awarded the first prize. The design provides for 24 beds, two wards of 10 beds, one of 3, and an isolation ward containing 1 bed.

CORN OIL IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

JOHN RITTER, M.D.
Instructor in Medicine, Rush Medical College.
CHICAGO.

The medical profession is fully conversant with the fact that, in the treatment of pulmonary tuberculosis, the oils and fats take foremost rank. All tissue waste, in excess of that in health, which always takes place during the active tuberculous process, must be met by an abundance of aliment to restore the metabolic equilibrium. Our chief reliance usually is placed on the ingestion of easily assimilable and readily digestible food. As food values the fats and oils are of the most importance. If the tuberculous patient refuses to take, or does not well tolerate, fats and oils which form part of the daily diet, such as butter, yolk of eggs, bacon, etc., then recourse must be had to some animal or vegetable fat given as a medicine.

Of animal oils, that obtained from the liver of the cod fish has for years been given the preference. Of late, the use of olive oil has come greatly into favor. Both cod liver oil and olive oil are expensive, and the price of these oils is, as a rule, beyond the reach of most tuberculous patients, as most patients suffering from pulmonary tuberculosis belong to the poorer classes. This has induced me to look about for an oil or fat which possesses all the good qualities and properties of either cod liver oil or olive oil, or of any other good vegetable oil, and which is inexpensive, palpatable, easily assimilated, well borne by the stomach and does not cause nauseous eructations. My attention was directed about a year ago to an oil obtained from corn or maize and I began to recommend and prescribe it to patients who applied at the Central Free Dispensary of Chicago and who were suffering from pulmonary tuberculosis. This was to be used in lieu of either cod liver oil or olive oil. From the fact of its inexpensiveness, it being about one-fourth the price of that of any other oil or fat usually prescribed in pulmonary disease, I wished to give corn oil a fair trial. I ascertained from reliable sources that the output of corn or maize oil is practically unlimited and it being only a by-product in the manufacture of starch minimizes its cost of production and makes the selling price proportionately low. The low price of maize oil, combined with all the good qualities of a palatable and wholesome oil, makes it the ideal oil for patients suffering from pulmonary tuberculosis.

I have given it not only to such as applied at the Central Free Dispensary for treatment, but also to such as came under my care at the Tuberculosis Institute and in all cases with equal gratifying result. I am convinced, from many close observations, that as a food or tissue builder it is fully equal to cod liver oil or olive oil. The ingestion of corn oil is well tolerated. It does not cause the nauseous eructations which usually follow the taking of cod liver oil, and the prolonged and increasing dosage is always well borne by the stomach.

Corn or maize oil (oleum mayidis, oleum zea mais) is obtained from ordinary corn. The amount of oil in corn varies from 3.5 to 6 per cent. The oil is found almost entirely in the germ which represents about 6.5 per cent. of the weight of the corn and about 50 per cent. of this germ is pure oil. It possesses all the properites of the fixed oils, being insoluble in alcohol or water, but very readily soluble in chloroform, ether or carbon bisulphid. Its color is light straw, it possesses a peculiar corn flavor, has very slight drying properties and a specific gravity of about 0.92, which is about the same as that of cod liver oil. Its viscosity is greater than that of olive oil. Its composition, like that of all vegetable fixed oils, is somewhat complex, mostly glycerids of the fatty acids, stearic, palmitic, oleic, archidic, etc. The chief source of maize oil is as a by-product in the manufacture of starch, dextrin and glucose. A small quantity is obtained when corn undergoes the process of fermentation in the manufacture of alcohol, and a like small quantity is obtained from the hominy mills.

The usual process of manufacture is very simple. In making starch the corn grain is steeped until the kernel is softened and the germ has assumed a tough, elastic condition. The warm steeping water is run off, the grain washed and then shredded apart and coarsely ground. This usually suffices to loosen the germ from the rest of the grain. The magma is now placed into tanks of rinsing water in which the starch granules settle rapidly to the bottom, while the light germs float off from the top. These germs are then washed, dried, ground and the oil removed by hydraulic pressure. The oil as obtained is very easily refined and clarified, simply by placing the expressed oil in large airtight containers for a definite time when the albuminous matter subsides or the subsidence of the albuminous matter may be hastened by the addition to the oil of an inert, insoluble earth, such as kaolin, decanting the clear oil and filtering.

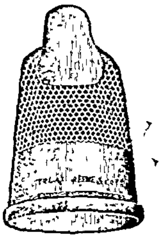
Every physician, with but limited experience with pulmonary patients, knows fully well that pulmonary tuberculosis is most prevalent among the indigent and needy poor and that the purchasing price of oils or fats, be it in the form of olive oil, cod liver oil, butter, etc., is not always within reach of these unfortunates; hence an oil or fat which possesses all the food values of the best oils or fats that are used in the building up of the wasting tissues, and at a cost to the purchaser of only one-fourth in money value, is undoubtedly an item which demands the careful consideration of every painstaking practitioner of medicine.

170 Colorado Avenue.

THIMBLE AND DISSECTOR FOR SURGEONS.

HARVEY P. JACK, M.D.
Consulting Gynecologist to St. James Mercy Hospital, Hornell.
CANISTEO, N. Y.

Every surgeon, doubtless, wishes almost daily that he had a long, strong, aseptic finger-nail and a thick insensitive callus on the end of one of his fingers. The thimble here illustrated is designed for the purpose of giving him a substitute for these. Except that the depressions in it are twice as large and deep, it is an ordinary thimble, with a quadrangular piece of steel firmly soldered in the position shown by the illustration. The steel projects one-fourth of an inch beyond the tip of the thimble and its edges are smoothly rounded. The thimble is designed for laying in interrupted or other sutures with a straight needle, the projecting tip being used to tuck in any everted edges. The instrument renders possible the sewing of tough structures without the aid of a needle holder and therefore with greater rapidity. Any long, sharp, straight needle may be used, but I have found it best that the needle should be two and one-half inches long. I have found the thimble very useful as a dissector for the purpose of picking up structures near large vessels and nerves.



Therapeutics

Elaterinum, U. S. P.

Elaterin is a neutral, active principle obtained from the juice of the fruit (a cucumber-like affair) of a trailing vine which grows in the countries around the Mediterranean Sea. One hundred of these cucumbers yield only a gram (15 grains) of elaterin, and it takes about eighty pounds of them to produce thirty grams (an ounce). Elaterium, or the dried juice of the cucumber, occurs in small, grayish fragments or masses, and has a tea-like odor and an acrid taste. Owing to its adulteration and variation in strength the elaterium as such is not now recognized in the Pharmacopeia, but its active principle, elaterin, is extracted, of which the juice contains from 25 to 35 per cent.

Elaterin occurs in small white scales or crystals, is of acrid bitter taste, is without odor, is insoluble in water, and but slightly soluble in alcohol.

It is irritant to the skin and mucous membranes, and frequently causes ulceration of the fingers and eyes of those working with it.

Internally its action resembles that of colocynth, but it is far more powerful. In small doses it acts as a stimulant to the gastrointestinal mucosa, increasing its secretion. It is also a stimulant to the pancreas and liver, perhaps reflexly. In larger doses it is irritant to the intestine, producing profuse watery stools, usually accompanied with griping and nausea, and occasionally with vomiting. Elaterium is one of the most powerful hydragogue cathartics, and large doses can produce dangerous prostration and even death. Elaterin acts when used hypodermatically, but is much more efficient when given by the mouth, as the bile seems to render it more active.

Elaterium is indicated when it is advisable to produce profuse serous discharges from the intestines, and has been used for many years in dropsies. It is especially valuable when there is effusion in the serous membrane cavities (pericardial, pleural and peritoneal cavities), and it also is often used successfully when there is general anasarca. Frequently diuretics will not act efficiently until free watery catharsis has relieved the pressure from exudates. Whenever this drug or any other is used to relieve dropsies it must be remembered that the intake of water in any form must be diminished. Elaterium has long been used in uremic conditions, whether there is dropsy or not, and it has often seemed that it relieved cerebral symptoms better than other hydragogue cathartics. It has been thought that it caused the elimination by the intestines of more of the products of metabolism, that the kidneys could not excrete, than any other cathartic. It has also been used to relieve cerebral and pulmonary congestions, acting as a revulsant. However, in cerebral congestion a quicker acting drug, as croton oil, is often better, and in dangerous acute pulmonary congestion any quickly acting hydragogue cathartic, as magnesium sulphate, will act as well, or better still, venesection as indicated.

The contraindications to the use of the elaterium are, gastric or intestinal inflammation, extreme exhaustion, any weak heart condition, and pregnancy. Unlike the action of croton oil, and unlike the action of the saline cathartics, after the movements of the bowels begin they tend to keep up, causing a large drain of water from the system which becomes very depressing, and sometimes can be stopped only by the hypodermatic use of morphin with atropin. This undesired action of elaterium prevents its frequent use.

The dose of elaterin is from 0.003 to 0.006 grams (from 1/20 to 1/10 grain), and it may be repeated once or twice at five-hour intervals, depending on the results.

Trituratio Elaterini is the only official preparation of elaterin, and contains 10 per cent. of the drug. The dose is 0.03 gram (½ grain).

It is not wise to use elaterin every day or even every second or third day, as it causes prostration and may cause intestinal inflammation. Consequently, if watery catharsis is desired daily, some saline hydragogue cathartic should be selected.

Nitrites.

The value of the nitrites seems to be in their ability to reduce the blood pressure. In some instances such reduction needs to be instantaneous, and in other conditions, as in arteriosclerosis and chronic nephritis, it is sometimes advisable to keep the blood pressure constantly reduced.

The official preparations are:

Amylis Nitris, nitrite of amyl, is a very volatile liquid which is administered by inhalation only, and the dose is a few drops on the handkerchief, or a glass capsule (or "pearl") is broken in a handkerchief and thus inhaled.

Spiritus Glycerylis Nitratis, the spirit of nitroglycerin, or glonoin, or trinitrin, as it is also termed, is a 1 per cent. solution of nitroglycerin, and the dose is one or two drops, administered in water.

Sodii Nitris, sodium nitrite, occurs in white opaque masses or as crystals. It is odorless and has a mild saline taste. It quickly changes to the nitrate on exposure to the air and is then unfit for use. It is very soluble in water, and the dose is 0.065 gram (1 grain).

Nitroglycerin is also offered in tablet triturate form, the dose ranging from 1/400 to 1/50 of a grain.

The action of amyl nitrite as a vasodilator is instantaneous, and with this action the heart is accelerated and the head feels full and throbs. It sometimes causes severe headache. If the amount inhaled is considerable the patient becomes faint, and always after nitrite of amyl has been used the patient should remain at rest for some time. The intensity of the action is soon over and, therefore, nitrite of amyl is indicated when instantaneous effect is desired, as typically in angina pectoris, or during the aura of an epileptic seizure. In the first instance, it obviates the danger of cardiac spasm, and in the second instance may abort the convulsion. In sudden cardiac failures, as in ether or chloroform narcosis, nitrite of amyl has sometimes been administered, but for such purposes is rarely indicated.

When a more prolonged vasodilator effect is desired, nitroglycerin is indicated, either administered hypodermatically in soluble tablet where the dose should rarely be more than 1/100 of a grain, or a tablet is allowed to dissolve on the tongue, or a drop or two of the spirit of nitroglycerin, or when slower action is desired, swallowed after a meal. Unless the condition is one of emergency and the quick stimulating effect of nitroglycerin is desired which will immediately be followed by dilatation of the peripheral blood vessels, nitroglycerin should be swallowed after a full meal. In this way the sudden, intense action with throbbing and fulness in the head is obviated. Nitroglycerin may be administered, when considerable dilator action is desired, every three or four hours, but three times a day, or perhaps better, four times a day (i. e., after each meal and at bedtime), is generally the frequency that is sufficient to continuously keep a high blood pressure slightly reduced. In hypertension in chronic endarteritis or arteriosclerosis it may frequently be noted that a small dose acts more satisfactorily than a larger one, i. e., many times 1/400 of a grain of nitroglycerin will act better than a larger dose. It must be remembered that such patients do not do well with low tension. Nitroglycerin is also very efficient and very successful in overcoming cardiac distress and dyspnea when there is aortic narrowing, when the left ventricle is not weakened.

Nitroglycerin also often relieves insomnia, when given at bedtime, by causing enough relaxation of the vessels to produce normal anemia of the brain—this in old people. Also, many times in continued fevers when alcohol seems indicated, nitroglycerin may be substituted to cause just sufficient dilatation of the surface vessels to aid in diminishing the temperature, which is one of the valuable actions of alcohol in fever.

It should be emphasized that the disagreeable, sudden and unpleasant effect of nitroglycerin may be obviated by giving smaller doses and by administering it after a meal and swallowing it with water; in other words, not allowing the medicine to be absorbed from the mouth.

The value of nitroglycerin in asthma to abort or to shorten the acute attack is well understood. The dose selected, perhaps 1/100 of a grain, should be administered every fifteen minutes until the severe headache or frontal throbbing is relieved, at which time the bronchial spasm will generally have relaxed.

While nitroglycerin is not so quick in its action as nitrite of amyl, and is more prolonged, its action is not so lasting as that of sodium nitrite, hence sodium nitrite is often used in its place. This drug should be administered three times a day, after meals, as:

℞.	gm.		
Sodii nitritis	1	or	gr. xv
Sodii bicarbonatis	20		ʒv

M. et fac chartulas 20.

Sig.: One powder, three times a day, after meals.

If the above alkali is not indicated as it often is in patients who need nitrites, any simple powder, as sugar of milk or any other combination, may be made that is deemed advisable.

H. Vaquez, *Archives des Maladies du Cœur, des Vaisseaux et du Sang*, January, 1908, advises the use of sweet spirits of nitre, spiritus ætheris nitrosi, not so much to decrease the vascular tension as for the general sedative effect on the circulation. If the sweet spirits of nitre is freshly prepared it may have some vasodilator effect, which is the only way that it could cause a sedative effect on the circulation, but for this purpose it is rarely used in the United States, the other preparations meeting better the indications for which nitrites are used.

Remedies for Asthma.—T. Brugsch contributes to the *Therapeutische Monatshefte*, December, 1907, an analysis of twenty-three of the various asthma remedies on the market. Most of them contain potassium iodid with or without some narcotic and a more or less harmless expectorant. The "inhalers" generally contain atropin, cocain or menthol, and the "smokers" some of the solanaceæ with potassium nitrate or nitrite. He gives working formulas for each, from his analysis, and adds that a similar compilation of analyses of proprietary remedies for gout might prove instructive.

a peculiar corn flavor, has very slight drying properties and a specific gravity of about 0.92, which is about the same as that of cod liver oil. Its viscosity is greater than that of olive oil. Its composition, like that of all vegetable fixed oils, is somewhat complex, mostly glycerids of the fatty acids, stearic, palmitic, oleic, archidic, etc. The chief source of maize oil is as a by-product in the manufacture of starch, dextrin and glucose. [For other information see second page following reading matter.]

SATURDAY, JULY 4, 1908.

FOURTH OF JULY ACCIDENTS.

After five years of active campaigning we commence our sixth annual compilation of statistics of Fourth of July accidents and fatalities. There is something gruesome and at the same time enraging to feel that to-day possibly hundreds of persons will be slaughtered and some 4,000 or 5,000 wounded and maimed who yesterday were care-free children preparing to make a Chinese holiday.

The supreme contempt of the American public for human life, as exemplified in our appalling daily slaughter by railroads, machinery, and preventable diseases, is nowhere so vividly shown as in this annual massacre. For the most part the responsibility can be laid at the doors of our inefficient municipal officials who make no earnest effort to check dangerous forms of celebration, although they are almost universally empowered by statute to do so. They will, with few exceptions, make this effort only when it becomes apparent that the public really demands it, and so the matter finally drifts back on public sentiment without waiting for which few public officers care to move. In a few cities there have been exceptional individuals in power who have demonstrated that it is not a difficult matter to check the dangers of the Fourth, and that any honest effort in this direction will receive public support and approbation.

Nevertheless we can look forward to having the responsibility of the care of some 5,000 wounded young "patriots" laid on the medical profession this year as every year, and we hope to see the steady and remarkable gain in the reduction of tetanus mortality continued. When THE JOURNAL first began its statistical studies five years ago the Fourth of July tetanus cases numbered 415, but after the publicity given these figures and the widespread demand for thorough surgical treatment and antitoxin prophylaxis in all blank cartridge and cannon cracker wounds, the morbidity dropped remarkably. From the 415 cases of 1903 the number was reduced to 105 in 1904, 104 in 1905, 89 in 1906, and 73 in 1907. As this improvement took place while the total number of accidents remained practically stationary, and with the deaths from causes other than tetanus rising steadily from 60 in 1903 to 102 in 1907, it is evident that the annual saving of 300 or more lives from tetanus has been accomplished in spite of public carelessness and official incompetence, through the activity of the medical profession. We have observed with no little satisfaction that nearly all the tetanus cases have developed in persons who did not receive medical attention in time to check the disease—a statement that we could not make five years ago.

Every annual compilation that we make of this subject adds to the now conclusive evidence that tetanus antitoxin is an almost infallible prophylactic, and that it should be used at the earliest possible moment for every case of penetrating wound caused by Fourth of July injury. Thorough surgical cleansing under anesthesia is, of course, imperatively demanded, but this alone, no matter how carefully carried out, can not give the absolute security that is assured when good surgery is supplemented by antitoxin prophylaxis. Since the Hygienic Laboratory has provided a standard for testing tetanus antitoxin, and has defined a unit for measuring the antitoxin strength, the value of the antitoxins on the market has now become something tangible, and their usefulness have been greatly increased. The unit is defined as ten times the least quantity of antitetanic serum necessary to save the life of a 350-gram guinea-pig for ninety-six hours against the official test dose of a standard test toxin furnished by the Hygienic Laboratory of the Public Health and Marine-Hospital Service. The Society of American Bacteriologists, in December, 1906, adopted a resolution in regard to the standardization of tetanus antitoxin and decided that the minimal immunizing dose for a case of possible tetanus infection should be 1,500 units.

We regret that it is not possible to hold out more hope of success in the curative treatment of well-developed tetanus, but in this respect the situation has changed but little in several years, and the mortality of tetanus resulting from these Fourth of July wounds is still probably over 90 per cent., although we can not secure reliable figures on that point. There are occasional cures reported that stimulate interest, but on investigation these are for the most part in cases with less virulent infections as shown by a long incubation period or mild symptoms. Tetanus, except in the largest hospitals, is encountered so rarely that most of the newer methods of treatment must be considered as still in the experimental stage. On the whole, the most useful method of treatment applicable by the general practitioner seems to be the subdural injection of repeated doses of antitoxin preceded by withdrawal of as much as possible of the toxic cerebrospinal fluid, and accompanied by injection of large doses of antitoxin subcutaneously. Rational symptomatic treatment with sedatives, narcotics, and, when necessary, with anesthetics, should also be carefully followed out. Controlling the spasms by intraspinal injections of eucain or cocain as proposed by Murphy, or magnesium sulphate as advocated by Meltzer, may also be found of value, but we need many more clinical reports on these methods. As tetanus is so rare a disease that the experience of any one person is of necessity limited, it is desirable that the experience of each be recorded and made available for all. We will welcome any case reports or other information concerning cases of Fourth of July tetanus that will aid us in compiling the record of this year's celebration.

AMERICAN MEDICAL ADMINISTRATION IN PANAMA THROUGH BRITISH EYES.

It is gratifying to read such a generous appreciation of American state medicine as is contained in an article on "America's Triumph in Panama," by John George Leigh.[1] Mr. Leigh, it will be remembered, contributed articles to the *Lancet*[2] explanatory of the climatic and hygienic problems facing the United States administration in the inaugural stages of work on the Isthmian Canal. He insisted that the success of the undertaking would depend not on the skill of modern engineers, of which there was no doubt, but on the question whether the health environment could be so ameliorated as to abolish the disastrous conditions that had caused the failure of previous attempts. He urged that the last word in the fateful decision then pending, between high-level and low-level plans, respectively, should be spoken "not by the aspiring engineer, but by the profession which will be held mainly responsible should the prophecies of ill be justified by events." The temporary success of the adherents of the sea-level scheme and its speedy abandonment justified Mr. Leigh's foresight.

In the present article he records the history of the canal from that date. In view of the clear-spoken responsibility which he had previously laid on the work of the medical department, and indirectly on the attitude that the government should adopt toward that department, his comment on the results as they actually befell is well worthy of reproduction. After recounting the reconstruction of the commission, consequent on the "unendurable and even dangerous" situation into which the project had fallen, by a lack of heed to the warning as to the paramount importance of the hygienic administration, Mr. Leigh continues: "All these appointments have been fraught with happy consequences, and none more so than that of Colonel Gorgas, whose promotion to the rank of commissioner must be regarded, not only as a well-merited personal compliment but also as a national recognition through the chief executive of the immense services which are being rendered to the United States in the prosecution of its great undertaking by members of the medical profession." It is to Colonel Gorgas' efforts and to his loyal support by the administration that Mr. Leigh attributes the fulfilment of his prophecy in 1905, that the canal would, "during construction, prove the most striking object lesson ever offered of the benefits to be derived from a well-organized sanitary organization associated with a great public work."

The article concludes: "In the lap of the gods rests the future of the Panama Canal enterprise. Whether it prove the great engineering triumph and commercial highway to which many of us look forward with confidence time alone will show, but of one credit history can never rob the United States. Among much good and evil it must record that it was under American administration that the knowledge and resources of modern science were applied to the hygienic redemption of the once noisome isthmus. Such fruits of labor in this direction have already been gathered that they promise to rival as a worthy monument of American achievement even the canal itself." We can thankfully accept this ungrudging praise, for we know it to be as just as it is generous.

A SPLENDID GIFT TO ADVANCE PSYCHIATRY.

Probably the phase of medical advance, in this age of progress, of which the world at large is least cognizant is that in psychiatry; and it is safe to affirm that in no country have greater strides in this branch of medicine been made than in the United States. They have, however, been unheralded by public clamor; rather, on the contrary, where the results of recent scientific research in that direction have been forced on the attention of the public, as by the attitude of the medical profession to the relations between crime and insanity, they have been greeted with indifference. But, for all that, the advance is real, and must sooner or later be acknowledged; indeed, the awakening is already at hand.

Significant, as well as munificent, is the recent splendid gift to Johns Hopkins University of Mr. Henry Phipps—to whose philanthropic interest in behalf of another great problem, tuberculosis, the Phipps Institute in Philadelphia, as well as the Phipps Dispensary for Tuberculous Patients at Johns Hopkins Hospital, bears practical and eloquent testimony. He now gives $750,000 to build a psychiatric addition to Johns Hopkins Hospital and to endow it for ten years with clinical, research and educational facilities, as was briefly noted in The Journal last week. The director of the psychiatric clinic and professor of psychiatry appointed by the trustees, on the recommendation of the medical faculty, to fill the new office established by this benefaction, is Dr. Adolph Meyer, of New York. It would certainly have been difficult to make a better selection. To a general culture broad beyond the average, Dr. Meyer adds a notable experience as a scientist and psychiatrist. After a distinguished academic career at Zürich, where he was born, including study in London, Edinburgh, Paris, Vienna and Berlin, he came to America in 1892 and at once rose to prominence, becoming in succession a teacher of neurology in the University of Chicago and pathologist to the Illinois Eastern Hospital; then director of the clinic and laboratory at the Worcester (Mass.) Insane Hospital and a teacher of psychiatry at Clark University, and, finally, director of the pathologic institute of the New York State Hospital, Ward's Island, and professor of psychiatry at Cornell University. His contributions to the literature of nervous and mental diseases are many and notable.

---

[1] Lancet, June 6, 1908, p. 1646.

[2] June 3, 10, and 24, 1905.

In accordance with a sound principle now becoming more and more general, Dr. Meyer and the architect of the proposed buildings will shortly make a tour of the principal psychiatric clinics abroad, with the view of starting the new institution from the most advanced point, in the matter both of building and of administration.

BACTERIAL THERAPY AND DIAGNOSIS OF GONOCOCCUS ARTHRITIS.

The strenuous application of opsonic therapy to clinical uses by persons of all degrees of qualification has led to a confused tangle of contradictory results and debatable conclusions, from which the solid facts are hard to isolate. Out of the confusion, however, certain facts have emerged definitely and prominently; one of these is the readiness with which hypersensitization to bacterial substance may be obtained, and the relation of this hypersensitization to the well-known tuberculin and mallein reactions. Another is the unquestionably favorable results that are sometimes obtained in certain tuberculous lesions, and in a few other forms of infection, from careful and judicious immunization with dead bacteria.

Acute infectious processes, as a rule, are much less likely to be favorably influenced by this method of treatment than chronic infections, even when produced by the same organism, and gonococcus infections constitute no exception to this rule. Bacterial therapy has given for the most part uncertain or no results in the treatment of acute urethritis and vulvovaginitis, although there are some who have been encouraged by their experience in this field. Gonococcus arthritis and periostitis, however, on account of their chronic course offer particularly favorable conditions for bacterial therapy, and here the results seem to be promising. Cole and Meakins observed favorable results in fifteen cases of gonococcus arthritis in which inoculations were given and systematic observations made on the opsonic index. Recently Irons[1] has reported forty cases of gonococcus infection, including thirty-one cases of arthritis, in which bacterial inoculation was tried, and the results were favorable, especially in the chronic forms of gonococcus arthritis. It was incidentally observed that massage of the prostate, when this organ is infected, has much the same effect as an injection of dead gonococci, being followed by a marked rise in the opsonic index of the blood and a favorable influence on any coexisting gonococcus infection. Presumably the massage causes an autoinoculation with gonococci, which results in an augmentation of the powers of resistance.

Besides the therapeutic results Irons has made another observation that seems to promise much of value in the diagnosis of gonococcus lesions. He noted that in patients suffering with gonococcus arthritis or other localized infections with the same organism, injection of dead gonococci is followed by clinical phenomena that are similar in many respects to those following injection of tuberculin in tuberculous patients, while no effects are produced by injecting dead gonococci into normal individuals. A slight rise of temperature and some malaise accompany an increase in the local symptoms in the joints, and sometimes there is a local reaction at the point of injection; with these manifestations there is a temporary lowering of the opsonic index, which is followed by a rise in the index and an improvement in the course of the disease. As gonococcus arthritis is often difficult of diagnosis, and establishment of the correct etiologic factor is of especial importance now that specific bacterial therapy is being found of value, this "gonococcus reaction" may be of great assistance in the diagnosis of arthritic conditions. Several cases are cited by Irons in which this reaction was found to point out the presence or absence of gonococcus infection. His conclusions, which are quoted below, are tempered with scientific conservatism.

"Clinically in a number of cases the injections of dead gonococci have seemed to be of distinct value. Many more series of cases must be studied before a definite opinion can be expressed, but the results obtained thus far seem to indicate that in certain cases at least of gonococcus arthritis recovery can be hastened by the injection of dead gonococci. No harm has appeared to follow the injections, and it is possible that the use of larger doses will be found desirable in some cases. With further work the limitations as well as the advantages of the method will appear, and it should be recognized that while it is attractive theoretically as a specific therapeutic measure, too much must not be expected of it in the way of marvelous cures. It should be used rather in conjunction with other general measures such as rest, aspiration of joints distended with fluid, massage of the prostate, and other surgical and general hygienic treatment. The reliability of the clinical gonococcus reaction as a diagnostic procedure will also be determined only after many tests. It has many points in common with the tuberculin reaction, and similarly, too, there may well be cases of gonococcus infection found which do not respond. It appears, however, to be well worth a trial. Should the reaction prove to be reliable, a valuable and much-needed aid will be at hand for the diagnosis of obscure joint, synovial and periosteal diseases."

---

INTERNATIONAL CONGRESS ON TUBERCULOSIS.

The International Congress on Tuberculosis which convenes in Washington, September 21 to October 12 and which has frequently been referred to in these columns, will, for many reasons, be a most notable meeting. The remark has been made that it will be somewhat surprising if such a congress can hold the attention of the public in the midst of what will doubtless be a spirited political campaign. It is to be hoped, however, that it will do this, for the meeting will be one, not merely of local, but of international importance. It will be participated in by experts in tuberculosis from all over the world, and America will be given an opportunity to learn from other nations the details of the organized fight against tuberculosis. In this respect, although we have made a creditable beginning, it must be admitted that, on the whole, we are somewhat behind other nations. It is expected that the work of the noted foreign visitors will not be limited to the congress, but that they will remain some time after the congress has closed and give the benefit of their experience in a series of addresses in the various cities of the country. The national government will take part and many of the states have already appointed representative committees. Those which have not done so should lose no time in perfecting arrangements for a complete exhibit of the measures which they are taking against the spread of the disease.

The fear is sometimes expressed that we are pushing the antituberculosis propaganda too far and inducing a veritable phthisiophobia. This apprehension has its justification, perhaps, in certain extreme measures which have been proposed, but when it is realized that the successful prevention of tuberculosis depends, not on mere quarantine measures, but on a genuine hygienic and social reform, it must be admitted that the movement is in little danger of going too far. One of the great benefits of the congress will be the incentive and the opportunity afforded to unify and coordinate the efforts of the different sections of the country so that all may work together in harmony and with the greatest benefit.

The congress should awaken in the general public a widespread interest and should emphasize the fact that the movement against tuberculosis is one which in its economic and humanitarian aspects belongs to the general public and not to any class. To this end it is to be hoped that the exhibition and popular lectures will attract wide attention.

Aside from the services of the congress in the interests of preventive medicine, we may expect important contributions to the pathology and treatment of the disease. The preliminary work of preparation has been done largely under the auspices of the National Association for the Study and Prevention of Tuberculosis and the thanks of the profession are due this organization for its efficient efforts. The best expression of this appreciation will be a determined effort on the part of every one so far as possible to make the congress a success.

CLEAN ADVERTISING—A SIGN OF THE TIMES.

We are glad to add to our already published instances another example of "sweet reasonableness" on the part of the press in regard to the question of cleaning up the Augean stables of advertising. Considering that the task is a costly one for those publications engaged in it, it is meet that it should receive public recognition and thanks when it is conscientiously performed. The instance to which we refer this week was brought to our notice by Drs. Boyer and Boyer of Indianapolis. One of this firm, a subscriber to a monthly periodical called *Reason*, published at Rochester, N. Y., called the attention of the publishers to the fraudulent nature of Actina, an advertisement of which that journal carried. The publishers replied courteously, thanking Dr. Boyer for directing their attention to it. They stated, however, that they had investigated the matter, so far as they were competent to do so, before accepting the advertisement, and added: "You must admit that such statements as you have made call for substantiation and proof that will convince any fair-minded person. It is clearly 'up to you.' Make good your assertion and we will gladly cease advertising this firm and tender you our most sincere thanks. Failing this, we shall send your letter with a note of explanation to the Actina Company, as you are doubtless aware it is actionable for libel. This is quite fair, is it not?" Quite fair, it would seem—fair alike to the legitimate demands of subscribers and to the just interests of advertisers, showing bias in neither direction, but a level-headed sense of justice and a desire for the right. The reply of Dr. Boyer was simple but effective. He forwarded a marked copy of the "Great American Fraud" reprint. Thereupon the Austin Publishing Company wrote to thank him, and stated that they "have decided to suspend the advertisements of the Actina Company, classing them as 'undesirable.'" They further ask permission to keep the booklet, "for use as a check for future advertisements of this nature." This is a noteworthy demonstration of three important points: 1, The awakening of the press conscience to the fact that it has a duty in the matter of fraudulent advertising; 2, the effectiveness of Mr. Adams' Great American Fraud series; and 3, the service that can be rendered to the cause by individual physicians who have the strength of their convictions. *O, si sic omnes!*

A CORONER ON OPERATIONS.

In our London correspondence[1] this week we are told that a British coroner is attracting attention among medical men by his attitude with regard to deaths due, directly or indirectly, to operations. The coroner's argument is that, with the great increase of surgical operations, some deaths are doubtless due to the operation itself and, therefore, come within the coroner's jurisdiction. In the case referred to by our London correspondent, such a well known man as Sir Victor Horsley was called on to testify in a case of death resulting from the removal of a brain tumor. The coroner directed the jury that a verdict of accidental death would be proper if the members of the jury were "satisfied that the operation was justifiable and that all due care had been taken." Even were such supervision as that suggested by this zealous officer either necessary or desirable, the idea of a jury of twelve men, possessing neither medical nor surgical knowledge, passing on the question as to whether an operation performed by one of the foremost surgeons of the day was "justifiable," is, in its last analysis, laughable. Equally ridiculous is the attempt on the part of the same men to determine whether or not "due care had been taken" at the operation. The whole system savors too much of that relic of barbarism that obtains in many of our state courts in which a jury of laymen pass on the question of an individual's sanity. It is conceivable that, in those cases in which the surgeon has been, justly or unjustly, the subject of censure, a coroner's jury composed of an equal number of intelligent laymen and of physicians might render a valuable service both to the public and to the medical profession. The idea, however, that a jury composed only of laymen is competent to pass judgment on cases involving so many abstruse and nice points of a purely technical nature is preposterous.

---

[1] Page 50.

Medical News

CALIFORNIA.

Fees Allowed.—In the circuit court recently, Dr. Peter C. Remondino, San Diego, was allowed $2,000 fees for professional services to the late George W. Crane. Dr. Remondino's claim originally made was for $3,900.

Unlicensed Practitioner Sentenced.—Thomas H. Storey, Los Angeles, is said to have been found guilty, May 15, of practicing medicine without a license and to have been sentenced to imprisonment for sixty days and to pay a fine of $500.

Medical Meetings.—The Alumni Association of the College of Physicians and Surgeons, San Francisco, has elected the following officers: President, Dr. Francis B. Williams; vice-presidents, Drs. Thomas Fletcher and Frederick C. Keck; secretary, Dr. Charles M. Troppmann, and treasurer, Dr. H. A. Mager. The Orange County Medical Association, at its annual meeting and banquet, held in Santa Ana, installed the following officers: President, Dr. John Wehrly, Santa Ana, vice-president, Dr. J. L. Beebe, Anaheim; secretary, Dr. Jessie M. Burlew, Santa Ana; treasurer, Dr. John L. Dryer, Santa Ana, and librarian, Dr. Howard S. Gordon, Santa Ana.

CONNECTICUT.

Typhoid Epidemic.—Typhoid fever is reported to be epidemic in Terryville. The health officer in making investigation as to the source of the epidemic, found that all the typhoid patients had procured their milk supply from one individual, and that a portion of this supply had been procured from a farm which has a typhoid history.

Society Meetings.—At the annual meeting of Litchfield County Medical Association, held in Winsted, the following officers were elected: President, Dr. Irving L. Hamant, Norfolk; vice-president, Dr. Salmon G. Howd, Winsted; clerk, Dr. Frank H. Lee, Canaan; and councilor, Dr. Edward H. Welch, Winsted.——At the one hundred and sixteenth annual meeting of Hartford County Medical Society, held in Hartford, the following officers were elected: President, Dr. Charles M. Wooster, Tariffville; vice-president, Dr. Charles D. Alton, Hartford; secretary-treasurer, Dr. Frederick B. Willard, Hartford; councilor, Dr. Oliver C. Smith, Hartford; censors, Drs. Thomas F. Kane, Hartford; Walter, G. Murphy, East Hartford; and Edward G. Fox, Wethersfield.——At the annual meeting of Middlesex County Medical Association, held in Middletown, the following officers were elected: President, Dr. James Murphy, Middletown; vice-president, Dr. Michael D. Murphy, Middletown; clerk, Dr. Arthur B. Coleburn, Middletown; censors, Drs. Miner C. Hazen, Haddon, and John E. Bailey, Middletown; secretary-treasurer, Dr. James T. Mitchell, Middletown; councilor, Dr. Frank K. Hallock, Cromwell; and delegates to the state society, Drs. Arthur B. Coleburn and Jeremiah F. Calef, both of Middletown.——The Hartford Celtic Medical Research Society was organized June 11, and the following officers were elected: President, Dr. Daniel F. Sullivan; vice-presidents, Drs. Edward J. Turbert and Thomas F. Welch; treasurer, Dr. P. R. McPartland; secretary, Dr. James F. Rooney.——The Willimantic City Medical Society was organized June 19 by the physicians of the city, and the following officers were elected: President, Dr. Theodore R. Parker; vice-president, Dr. T. Morton Hills, and secretary-treasurer, Dr. Clarence E. Simonds. A committee was appointed to draft a constitution and by-laws, and the organization will be completed July 6.

DISTRICT OF COLUMBIA.

Recommended to Mercy.—Dr. Robert C. Anderson, Washington, indicted for house-breaking, is said to have been convicted June 11. The jury recommended him for mercy and requested that his mental condition be made the subject of official inquiry.

Unlawful Practitioner Sentenced.—Edward Leon Thompson, known as "Dr. Leon," who was recently convicted for performing an illegal operation on a colored woman, is said to have been sentenced, June 5, to imprisonment for five years in the penitentiary.

Dismissed from Service and Imprisoned.—Assistant Surgeon David A. Spear, U. S. Navy, charged with forging endorsements on pay checks, and who is said to have admitted having stolen from officers, and whose defence was mental incompetency from drink, is said to have been found guilty and sentenced to dismissal from the service and to imprisonment for one year.

ILLINOIS.

Large Class Examined.—At the Illinois State Board of Health examination, held in Chicago, June 24 and 25, there were 365 applicants, making the largest class on record to take the examination.

Fined for Prescribing Beer.—Dr. Roy C. Richards, Hopedale, accused of violating the "Dram Shop Act" by prescribing beer for a patient, is said to have pleaded guilty of technical violation of the law, and to have been fined $20 and costs.

Bids for Antitoxin.—The State Board of Health, through its secretary, Dr. James A. Egan, Springfield, is advertising for sealed proposals for diphtheria antitoxin for free distribution by the board. The legislature has appropriated $30,000 for this purpose.

Smallpox.—Elgin reports 18 cases of smallpox and 8 houses under quarantine.——Joliet still has 9 cases of smallpox; seven of the patients are in the Isolation Hospital and all are on the road to recovery.——Four cases of smallpox are reported at the Rock Island County Infirmary.

Tribune Hospital Opened.—The fourth consecutive season of the Tribune Summer Charities at Algonquin was inaugurated the first week in June. Building operations of the second building of the group have already been commenced. This building is to be a central pavilion, containing a dining hall, diet kitchen, laundry, general offices, etc.

Chicago.

Fire in Medical College.—A fire on June 21, originating in the clinical laboratory of the College of Physicians and Surgeons, caused considerable alarm to patients in the hospitals near by, although no one was injured. The total loss was about $3,000.

Vaccinators Invade Black Belt.—On June 25 a hundred physicians, under the direction of Drs. Heman Spaulding and I. Donaldson Rawlings of the department of health, made a house-to-house inspection of the territory lying between State and La Salle and Sixteenth and Forty-fourth streets. Every house was visited and the tenants were compelled to be vaccinated unless they could show satisfactory scars.

Communicable Diseases.—A total of 393 cases of communicable diseases was reported to the department during the week, 72 fewer than for the preceding week. To this total, measles contributed 177; diphtheria, 71; scarlet fever, 44;

whooping cough, 36; tuberculosis, 26; chickenpox, 22; typhoid fever, 12; smallpox, 2, and miscellaneous diseases of minor importance, 3. Of the two cases of smallpox, both patients were unvaccinated colored men, and in both cases the disease was apparently contracted outside of Chicago.

Personal.—Dr. G. R. Bailey obtained first place, Dr. H. B. Thomas second, Dr. Norman Kerr third, and W. R. Cubbins fourth in the civil service examination for the orthopedic surgery service at Cook County Hospital.——Dr. and Mrs. Arthur H. Brumback leave for Europe early in July.—Dr. E. C. Dudley and son expect to sail for Havre, July 18.——Drs. William A. Evans and George W. Webster have been elected members of the executive committee of the Chicago local advisory committee of the American Health League.

Mortality of the Week.—During the week 508 deaths were reported from all causes, or 53 more than for the preceding week, equivalent to an annual death rate per 1,000 of 12.23. The chief increase in mortality was from diarrhea diseases of infants and young children. Violence (including suicide) led the death causes with 55; consumption caused 47; acute intestinal diseases and pneumonia, each, 41; heart disease, 38; nephritis, 35; and cancer, 25. Eleven deaths were due to sunstroke; 12 to diphtheria; 7 each, to measles and typhoid fever; 6 to whooping cough, and 3 to scarlet fever.

Fourth-of-July Wounds.—The bulletin of the health department urges strongly the proper care of every Fourth-of-July wound, no matter how insignificant. The procedures advocated are as follows: Free incision of every wound; careful and thorough removal of every particle of foreign matter; thorough cauterization of the wound with 25 per cent. carbolic acid solution; application of a loose wet pack of 2½ per cent. carbolic acid solution; and the administration of a full dose of antitetanic serum. The wound should not be closed in any way and the dressing and packing should be renewed every day.

INDIANA.

Society of Social Hygiene.—The Indiana Society of Social Hygiene was organized at Indianapolis early in April, with the following officers: President, John H. Holliday; vice-presidents, Rev. Edwin Hughes and Hon. L. C. Walker; secretary, Homer G. Hamer; treasurer, Frank D. Stalnaker; official lecturer, Dr. Charles S. Woods.

Hospital Damaged.—The patients in St. Vincent's Infirmary, Indianapolis, were thrown into a panic, June 6, by a series of explosions in a gas plant, and one patient, one nun and four attendants were injured by flying débris, following the explosion. The coolness of the nuns and other attendants in the hospital alone prevented serious disaster.

Communicable Diseases.—Four new cases of smallpox are reported from Landesville.——Smallpox is still reported from Crawfordsville.——The smallpox epidemic in the southern part of Carroll County is now said to be under control.——Two new cases of smallpox were reported in Fort Wayne, June 9.——Fort Wayne reports sixteen cases of scarlet fever.

Health Officers' School.—The annual school for health officers of the state, under the auspices of the State Board of Health, was held in Indianapolis, May 14, nearly 400 officers being present and receiving instruction. Papers on various sanitary subjects were read and discussed, and the filtration works of the Indianapolis Water Company were visited.

May Death and Disease.—The most prevalent diseases in Indiana during May were rheumatism, tonsillitis and bronchitis. The total number of deaths were 2,694, equivalent to an annual death rate of 11.8 per 1,000. During the month 275 cases of smallpox were reported in 33 counties, with no deaths. Tuberculosis caused 389 deaths; typhoid fever, 27 deaths; diphtheria, 9 deaths; and violence, 221 deaths. There were 24 murders, 4 suicides, 33 deaths from railway accidents, 4 from street car accidents, 5 from lightning and electricity, 20 from burns and scalds, and 23 from drowning.

IOWA.

Acquitted.—Dr. Elijah M. Heflin, Calmar, charged with having performed a criminal operation on a Miss Kopet, was found not guilty by a jury at Decorah.

Commencement.—At the annual commencement exercises of Keokuk Medical College, May 26, a class of 38 was graduated.——Sioux City Medical College, at its annual commencement exercises, June 4, graduated a class of 9. Rev. Willis S. McFaddin delivered the doctorate address.

Jury Disagree.—After being out forty-eight hours, the jury in the case of Mrs. Annie Arp, asking damages of $50,000 from Drs. Alphonse L. Hageboeck, Julius T. Haller and J. H. Meyhaus, Davenport, on account of injuries alleged to have been the result of leaving a surgical sponge in the body of the husband of the plaintiff, during an operation for appendicitis, reported that they were unable to agree, and were discharged.

Personal.—Dr. Jerger, Waterloo, is about to take a year's trip around the world, via the west.——Dr. Rose H. Rice, Council Bluffs, has been elected supreme physician of the Woodman Circle, to succeed Dr. Jenny Califas, resigned.——Dr. Lawrence W. Littig, Iowa City, is reported to be seriously ill with septicemia.——Dr. O. J. Ruth, Keokuk, was operated on at St. Joseph's Hospital, May 24, for cholelithiasis.——Dr. Charles J. Cooney has been elected health officer of Oelwein.——Dr. Frank E. St. Clair, Hampton, is reported to have been seriously injured in a runaway accident.——Drs. Joseph M. Emmert and C. L. Campbell, Atlantic, have been appointed physicians for the A. N. & S. Railway.——Dr. S. S. Lytle, Iowa City, has been chosen director of the Iowa Department, G. A. R.

KANSAS.

Communicable Diseases.—Measles is reported to be epidemic in and around Culver.——There are said to be six cases of smallpox in one house in Leavenworth.——Rock Creek is reported to be free from contagious diseases.

Personal.—Drs. Guy L. Millington, Wellington, and Edwin B. Packer, Osage City, have been appointed members of the State Board of Medical Registration and Examination.——Dr. Judson C. Cole, Effingham, has been appointed health officer of Effingham and Atchison County.——Dr. A. B. Occhali has located at Stockton, succeeding Dr. J. C. Hinkle.

KENTUCKY.

Heavy Damages Claimed.—A. T. Poole, administrator of the late Dr. Henry J. Poole, Robard, has brought suit against the Louisville and Nashville Railway for $20,000 damages for the death of Dr. Poole, who was run over and killed by a train in December last.

State Hospital Changes.—Dr. Robert L. Willis, Lexington, has been appointed by the State Board of Control for Charitable Institutions, superintendent of the Eastern Asylum for the Insane, Lexington, vice Dr. John S. Redwine.——The following officers of the Lakeland State Hospital for the Insane have been reappointed: Superintendent, Louis H. Mulligan; assistant physicians, Dr. W. E. Gardner, John K. Wood and Louise B. Trigg, Glasgow.——Dr. Thomas W. Gardiner, Madisonville, has been appointed superintendent of the Western Kentucky Asylum for the Insane, Hopkinsville, vice Dr. James W. Stephens.

LOUISIANA.

Lepers Cured.—In the annual report of the Leper Home of the State of Louisiana, it is stated that one patient had been discharged cured, and that five others were practically well, but were still being held for observation.

Faculty Changes.—Dr. Isadore Dyer has been elected dean of the faculty and Dr. Gustav Mann, assistant professor of physiology in Oxford University, has been made professor of physiology in the Medical Department of the Tulane University of Louisiana, New Orleans.

Against Tuberculosis.—A branch of the Antituberculosis League of New Orleans was established at Winnfield, June 12, with Dr. Jonathan J. Peters, president, and Dr. Isaac E. Seiss, vice-president.——A branch of the Louisiana Tuberculosis League was organized at Bunkie, June 9, with Dr. E. Stanley Matthews, president.

Personal.—Dr. Robert P. Jones has been appointed a member of the Board of Health of Clinton.——Dr. A. A. Aucoin, Plattenville, has been elected president of the Assumption Parish Board of Health.——The school board of New Orleans has elected Dr. Edmond Moss chief inspector, and Drs. Edward McCarthy and J. J. Wymer inspectors of school children.

Organization.—The Attakapas Clinical Society was organized at New Iberia, June 10, with the following officers: President, Dr. Henry A. King, New Iberia; vice-presidents, Drs. Robert D. Voorhies, Lafayette, and T. T. Roussel, St. Mary's Parish; and secretary-treasurer, Dr. T. J. Williams. The American Medical Association's principles of ethics were adopted by the society.

Alumni Meeting.—At the meeting of the Charity Hospital Alumni Association, held in New Orleans, the following officers were elected: Dr. James M. Batchelor, New Orleans, president; Drs. Arthur A. Herold, Shreveport, and Herman B. Gessner, New Orleans, vice-presidents; Dr. Charles N. Chavigny, New Orleans, secretary; Dr. Philip W. Bohne, New Orleans, treasurer, and Dr. Espy M. Williams, Patterson, historian.

MAINE.

New Health Officers.—Dr. Harris J. Milliken has been elected city physician of Bangor.——At the annual meeting of the Portland Board of Health, Dr. Edward J. McDonough was elected chairman.——At the annual meeting of the Westbrook Board of Health, Dr. Albion E. Cobb was elected secretary.

State Association Meeting.—The fifty-sixth annual session of the Maine Medical Association was held at Bangor, June 10 and 11, under the presidency of Dr. Barzillai B. Foster, Portland. The annual oration was delivered by Dr. Hobart Amory Hare of Philadelphia on "Hold Fast to that Which Is Good in Diagnosis and Therapeutics." The following officers were elected: Dr. Alfred D. Sawyer, Fort Fairfield, president; Drs. Calvin P. Thomas, Brewer, and Stanley P. Warren, Portland, vice-presidents; Dr. W. Bean Moulton, Portland, secretary, and Dr. Edwin W. Gehring, Portland, treasurer. It was decided to hold the next annual meeting in Portland.

Society Meetings.—The forty fourth annual meeting of Somerset County Medical Association was held in Skowhegan, June 18, when the following officers were elected: President, Dr. Walter S. Milliken, Madison; vice-president, Dr. Leander A. Dascomb, Skowhegan; secretary-treasurer, Dr. Howard C. Taggart, Skowhegan; censors, Drs. Charles A. Moulton, Hartland, Warren G. Sawyer, Madison, and David S. Hunnewell, Madison.——At the annual meeting of Kennebec County Medical Association, held in Augusta, the following officers were elected: Dr. Theodore E. Hardy, North Vassalboro, president; Dr. Herbert E. Milliken, Waterville, vice-president; Dr. Wellington Johnson, Augusta, secretary-treasurer; and Drs. Virgil C. Totman, Oakland, Richard H. Stubbs, Augusta, and Asa B. Libby, South Gardiner, executive committee.——A medical club has recently been organized among the younger practitioners of Portland, with seven charter members.

MARYLAND.

Smallpox Near Baltimore.—Dr. James F. H. Gorsuch, Fork, health officer of Baltimore County, reports the smallpox epidemic in the river suburbs as well under control, 15 patients being cared for in tents and 10 in the State Quarantine Hospital.

Election of Officers.—At the nineteenth annual meeting of the Baltimore and Ohio Association of Railway Surgeons, held in Chicago recently, Dr. Franklin B. Smith, Fredericksburg, was elected president, and Dr. T. Murphy, Relay, secretary-treasurer.

Physician Wins Suit.—In the suit brought for $10,000 damages against Dr. Adolph G. Freedom, for alleged improper treatment in a case of diphtheria, whereby the son of the plaintiff is said to have died, the jury, by instruction of the court, returned a verdict for the defendant.

Vaccine Physicians Appointed.—Drs. Foster Sudler, Sudlersville; William G. Coppage, Church Hill; Ernest F. Smith, Centerville; John R. Benton, Stevensville; Roland H. Ford, Queenstown; Walter H. Fenby, Ruthsburg, and E. A. Landers have been appointed vaccine physicians for Queen Anne's County.

Health Bulletin.—The first series of health bulletins issued by the Medical and Chirurgical Faculty of Maryland, appeared in the Baltimore *Sun*, June 25, and was entitled "Modern Medicine Aims to Prevent Diseases as Well as to Cure Them." The second appeared June 28, and was on "Lockjaw." The articles appeared anonymously.

Baltimore.

Alumni Election.—The Alumni Association of the University of Maryland School of Medicine held its annual meeting and banquet, May 29. Dr. Thomas M. Chaney, Chaney, of the class of 1866 was elected president.

Personal.—Dr. Robert S. Kirk has been re-elected superintendent, and Dr. John Roth, assistant superintendent, of the Eastern Dispensary.——Drs. Roland B. Whitridge and C. Urban Smith have sailed for Europe.——Dr. Benjamin F Lovelace, assistant in the department of chemistry, Johns Hopkins University, has been appointed professor of chemistry in the University of Alabama.——Dr. Frederick H. Baetjer sailed June 2 for Italy.——Dr. D. Webster Cathell has been ill at the Church Home Infirmary.——Dr. Philip S. Evans, Jr., a medical missionary in China, has returned to Baltimore, after an absence of seven years.——Dr. William D. Booker, who is now in Florence, reports that he is much improved in health.

MASSACHUSETTS.

Personal.—Dr. D. C. Rogers has been appointed assistant in applied psychology in Harvard University.——Dr. Prentiss, Harvard University, has been appointed assistant professor of anatomy at the Northwestern University Medical School.——Dr. F. C. Shattuck, professor of clinical medicine, Harvard Medical School, has had conferred on him the degree of LL.D. by the University of Cincinnati.

NEW YORK.

Death of Noted Optician.—Dr. Henry Lomb, one of the founders of the Bausch and Lomb Optical Company, Rochester, and one of the most prominent men in his line in the United States, died June 13, aged almost 80.

Typhoid at Auburn.—For the past ten years typhoid fever has pretty steadily prevailed in this city, there being from 21 to 68 cases yearly. This year the outbreak occurred earlier than usual, and by the latter part of May there had been 33 cases, with six deaths. This led the health officer to investigate. As there were only two articles universally used, milk and water, he supposed one of these to be responsible. The milk came from 14 different sources, and it did not seem reasonable to suppose all of these contaminated, so the water supply was investigated. It was found that at the head of Lake Owasco, from which the city supply is taken, there was a large influx of crude sewage. There seemed, therefore, but little doubt but that this was the source of the disease.

New York City.

Another Healthy Week.—Fewer persons died during the week ended June 20 than at any time since the establishment of the Health Department. There were 332 deaths less than for the week ended June 21, 1907. The rate was only equivalent to an annual mortality of 13.45 per 1,000. The Borough of Manhattan showed a lower death rate than any of the other boroughs.

Blow to Greater Bellevue Hospital.—The State Charities Aid Association has reported in opposition to the proposed enlargement of Bellevue Hospital and large expenditures for local and general hospitals in this city. They desire to have emergency relief stations in different parts of the city and eventually to replace these by local hospitals. The report provides for hospital needs until 1920.

Cooperation for the Suppression of Noises.—The health board has appealed to the police commissioner for aid in combating the noise nuisance. The noises are classified under four heads: the unnecessary whistling from boats in the rivers and harbor, the carting of loose metal through the streets, automobile horns and whistles and the noise incident to the Fourth of July. A patrolman will be stationed in front of every hospital on July 3, 4 and 5.

Poster War on Tuberculosis.—The committee on the prevention of tuberculosis have hit on a novel way of educating tenement dwellers in regard to the prevention of tuberculosis. A brilliant lithograph of a scene in Venice, around the border of which is printed advice in large type, has been distributed to 10,000 Italian families. The committee thinks the poster will be seen and its advice read by at least 50,000 persons. The same idea will be carried out among other nationalities.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended June 20, 428 cases of tuberculosis, with 143 deaths; 841 cases of measles, with 21 deaths; 377 cases of diphtheria, with 30 deaths; 410 cases of scarlet fever, with 25 deaths; 48 cases of whooping cough, with 3 deaths; 38 cases of typhoid fever, with 9 deaths; 7 cases of cerebrospinal meningitis, with 7 deaths; one case of smallpox and 108 cases of varicella, making a total of 2,258 cases, with 238 deaths.

Personal.—Dr. Adolph Meyer has been appointed director of the newly founded psychiatric clinic of Johns Hopkins University, Baltimore. Since 1902 Dr. Meyer has been director of the pathologic institute of the State Hospital of New York on Ward's Island. Since 1904 he has been professor of psychiatry in the medical department of Cornell University.——Warren Brown, Ph.D., assistant professor of psychology in Columbia University, has been appointed instructor in psychology in the University of California.

TENNESSEE.

Commencement.—At the commencement exercises of Tennessee Medical College, Knoxville, a class of 5 was graduated, Dr. W. Wallace Derrick, dean of the faculty, conferring the diplomas.

Personal.—Dr. A. C. Alexander, chief surgeon, and Dr. T. B. Hughes, assistant surgeon, of the Soldiers' Home, Johnson City, have resigned.——In the case of Dr. Abraham W. Boyd, Chattanooga, who was sued for $5,000 damages for alleged improper care of a patient, the jury returned a verdict in favor of the defendant.——Dr. J. Herman Feist, Nashville, who has been confined in jail for fifteen months past, has been released on bonds of $25,000.

New Medical Journal.—The advent of the *Southern Medical Journal* is announced at Nashville, the editorial staff consisting of Drs. Duncan Eve, Sidney S. Crockett, A. Bennett Cooke, William Litterer, Samuel M. Bloomstein, Joseph P. Keller, Marvin M. Cullom, William D. Haggard, Giles C. Savage, Lucius E. Burch, Hilliard Wood, George H. Price, Perry Bromberg, and George C. Trawick. The editor-in-chief will be Dr. John A. Witherspoon, and Drs. Worcester A. Bryan and James M. King will be the managing editors.

TEXAS.

Commencement.—The seventeenth annual commencement exercises of the Medical Department of the University of Texas, Galveston, were held May 30, when a class of 25 was graduated. Dr. James E. Thompson delivered the faculty address and President David F. Houston conferred the degrees.

Personal.—Drs. Wood and William A. Garrett, Houston, were painfully injured in a runaway accident, June 12.——Dr. James Greenwood, Jr., Seguin, has been appointed demonstrator of medicine in the University Medical Department, Galveston, and assistant physician to John Sealy Hospital, vice Dr. Wallace Rouse, deceased.——Drs. Joseph R. Stuart and John D. Duckett have retired from the board of health of Houston.

Alumni Meeting.—At the annual meeting of the Alumni Association of the Medical Department of the University of Texas, Galveston, held May 29, the following officers were elected: President, Dr. David H. Lawrence, Galveston, and secretary-treasurer, Dr. Henry Hartmann, Galveston. It was decided that an effort should be made to have a special meeting of the alumni in Galveston in May next, on the occasion of the meeting of the state medical association.

WASHINGTON.

Personal.—Dr. Aug. J. Ghiglione, Seattle, has gone to New York City to be away several months.——Dr. F. S. Burns has been made chief medical inspector of the health department, Seattle.

Prevention of Tetanus.—The health commissioner of Seattle, Dr. J. E. Crichton, has issued notice that in every case of wound from fireworks or premature explosion of revolvers or pistols, the victim immediately be inoculated with antitetanic serum.

Hospital Notes.—The contract for the construction of the new three-story addition to King County Hospital, Georgetown, has been awarded, to cost $44,273.——It is proposed to ask the state legislature for an appropriation to build a hospital for the criminal insane.——The new open-air house of the Orthopedic Hospital Society of Seattle, was formally opened to public use, June 3. The building is intended for convalescents from the orthopedic ward of the Seattle General Hospital, and will accommodate 8 patients.

WISCONSIN.

Personal.—Dr. Warren B. Hill has been elected dean of Milwaukee Medical College, vice Dr. William H. Earles, deceased.——Dr. Samuel Bell, Beloit, has been elected medical director of the Department of Wisconsin, G. A. R.——Dr. William F. Becker, Milwaukee, has been reappointed president of the Milwaukee Hospital for the Insane.——Dr. Andrew C. Mailer has been appointed health officer and city physician of De Pere.

Commencement Exercises.—The graduating exercises of the Milwaukee Medical College, Medical Department of Marquette University, were held at the Davidson Theater, May 25. Rev. James McCabe, president of the university, conferred degrees on a class of 50, and the doctorate address was delivered by Dr. William A. Evans, health commissioner of Chicago. The program of the graduation exercises was arranged in the nature of a memorial to the late dean, Dr. William H. Earles. A dinner in memory of Dr. Earles was held at the Plankinton House, June 23, at which Dr. H. L. Banzhaf officiated as toastmaster, and addresses were made by Dr. W. Augustus Evans and Truman W. Brophy, Chicago, Mayor Rose and John H. Moss.——The fifteenth annual commencement exercises of the Wisconsin College of Physicians and Surgeons were held May 28, when a class of 9 was graduated. The dean, Dr. Thomas C. Phillips, assisted the president, Dr. A. Hamilton Levings, in conferring the degrees. It was announced that a large free dispensary would be established by the college on property now owned by the institution on Reservoir Ave., adjoining the college buildings.

GENERAL.

Another State Journal Established.—The first number of *The Journal of the Oklahoma State Medical Association* was issued the first of the month. It contains an account of the recent meeting of the state association, the address by the president, the proceedings of the house of delegates, and a full roster of the members of the state association, with a list of the county societies and officers, as well as a number of original articles, case reports, news items, etc. The journal is edited by the secretary of the state association, Dr. Eugene O. Barker, Guthrie, who has as his assistants the board of councilors of the state association. This journal will certainly prove of great assistance to the association in carrying on its work in Oklahoma, and will be of great value to the members. The new journal is issued in magazine form, 6½x10, and typographically is a credit to the association.

Pan-American Congress Routes.—Dr. Ramon Guiteras, secretary, 75 West Fifty-Fifth street, New York, announces these routes to and from the Fifth Pan-American Congress at Guatemala, Aug. 5 to 10, 1908: *New York by train to New Orleans;* thence by United Fruit Company steamer to Puerto Barrios on the Gulf; thence by train to Guatemala City, $56, plus the price of food and sleeper on train to New Orleans. Time, seven days. *From the Middle West*, rates and time about the same as above. Steamers leave New Orleans for Puerto Barrios Thursday mornings at 10 o'clock. *From San Francisco* by boat to San Jose; thence by train to Guatemala City, $76.50. Time, eleven days. *Return trips*, by the same routes and at the same expense as above; or by train from Guatemala City to San Jose; thence by boat to Salina Cruz, a Mexican and Pacific port; thence overland to City of Mexico. Cost, $53. Or: From City of Mexico to New York entirely by rail, including berth, $80. Total cost from Guatemala City to New York City, $133. Probably the same to the middle west. Or: From City of Mexico to Vera Cruz, $10; thence by Ward Line Steamer to New York, stopping at Yucatan and Cuba, $60. Total cost from Guatemala City to New York City, $123. Hotels at Guatemala charge $2 and $4 a day. The Capitol at Guatemala is situated on a plateau, one mile above sea level. August is the time of year known as the "cunicula," when there is no rain and the heat is not as great as in our own southern states.

FOREIGN.

Plague in China.—Vice-Consul Baker reports that plague has become epidemic at Amoy. This disease is also present in Hongkong.

Quadricentennial of Madrid University.—Preparations are being made in Spain to celebrate on an extensive scale the four hundredth anniversary of the founding of the University of Madrid, Oct. 18, 1508.

Medal for Rubner.—The professor of hygiene at Berlin, Dr. Max Rubner, has been awarded the Liebig gold medal by the Bavarian Academy of Sciences for what he has done for veterinary science. Rubner's research was on the metabolism of the higher animals, and it unexpectedly developed some new points of view for the proper feeding of cattle.

Physician Beloved by a Community.—The *Gazzetta degli Ospedali* relates that the entire population of the town of Stiava, in the province of Lucca, Italy, gathered recently at the town hall to protest against the removal of the district physician (medico condotto) who had been ordered to another point. He had endeared himself to the community by fifty years of service, and the district was in a tumult until the order was countermanded.

Memorial to Annandale.—A reference to the memorial to the late Dr. Annandale, professor of clinical surgery in the University of Edinburgh, appeared in The Journal, May 9, 1908, page 1535. A sum of $1,160 has been subscribed and $840 remains to be found. Subscriptions may be forwarded to Dr. H. M. D. Watson, at 13 Rutland Square, Edinburgh, secretary and treasurer to the committee. The subscription list will close on July 31.

Medical Study Trips Abroad.—The Italian Society for Climatology and Physical Therapy has organized an educational excursion to some of the Italian watering places, starting at Milan this week. The eighth German medical study trip will include a visit to the Canary Islands. It is in charge of Professor von Strumpell, of Breslau, and will leave Hamburg September 1. A large party of French physicians recently visited London on the occasion of the inauguration of the Franco British exhibition.

Zaufal Retires.—At Prague, May 23, the clinic for diseases of the ear celebrated its thirty fifth anniversary, and at the same time, Prof. E. Zaufal retired from its leadership. Zaufal founded the clinic in 1873, and it has always taken a leading place in surgery of the ear. He is said to have been the first to make bacteriologic examination of middle ear affections and to operate in otogenic sinus thrombosis. He is now 71, and the occasion proved an ovation from scientific societies, and the profession generally in the German speaking countries. It is described in the *Prager med. Wochenschrift*, June 4. Zaufal was one of the founders of this journal thirty-three years ago.

Decisions of the Prussian Medical Tribunal of Honor.—Among the recent decisions is one acquitting a physician of unethical conduct when he increased the amount of his bill, as it was returned to him by the patient for specification of details. The total was not exorbitant. In another case a surgeon found that no dressings had been supplied for the operation he was performing and he made a caustic remark on the bad management of the director of the hospital in his presence. This case was dismissed as trivial. In another case a physician wrote on his certificate for a victim of industrial trauma "If Dr. X says that there are no symptoms on the part of the nervous system he either overlooked this striking symptom complex or did not wish to see it." The court regarded the last seven words as a serious insult to another physician and imposed a corresponding penalty, although conceding that scientific criticism of the certificates of other physicians is allowable.

The Irish Medical Association.—The annual meeting of the Irish Medical Association was held in Dublin June 10 with Prof. J. S. McArdle vice president, in the chair. Sir William Smyly, the incoming president, in his address referred to the progress being made in the campaign against tuberculosis, and mentioned especially the work done by Lady Aberdeen. In regard to his own specialty of midwifery, he pointed out that improvement is needed. The old types of practitioner and midwife have passed away and those now engaged in the work are fully alive to their responsibilities. But even now he said, the average mortality of childbirth is nearly double that which exists in well managed hospitals. He recommended practical clinical examinations in lying-in hospitals and regular attendance at these institutions. He expressed the opinion that the midwives act would prove a beneficial measure to poor women in Ireland who are dependent on midwives for care during labor.

LONDON LETTER.

(From Our Regular Correspondent.)

London, June 13, 1908.

The Sanitary Work of the Port of London

The work of the Port Sanitary Committee of London in a single year is considerable. For its performance there are a medical officer, five assistant medical officers, three food inspectors, eight sanitary inspectors, and a large staff of nurses at Gravesend Hospital. The work of preventing disease from entering London by the river goes on day and night. Last year 37,000 visits of inspection were paid—18,000 to vessels from foreign ports and 19,000 to "coastwise" craft and 252 cases of infectious disease about to enter the port were detected. A constant war is waged against rats. Nearly 53,000 were destroyed last year—15,000 in the docks and 38,000 on vessels. Dr. Williams, the principal medical officer, in his report for 1907 makes the interesting statement that scurvy has practically disappeared from the mercantile marine. He attributes this to the fact that voyages are shorter and that better methods of preserving food are adopted. An important branch of the port authority's work is the seizure and destruction of unsound food. Nearly 3,000 tons of food were condemned. This included 3,000 carcasses of mutton, 5,000 packages of fruit, 1,000 chests of tea, and 7,300 eggs, besides rabbits, fish game and vegetables. The cost of the sanitary administration in the year was $50,000.

The Crusade Against Tuberculosis in Ireland.

The crusade against tuberculosis in Ireland has been described in previous letters. The most important step was the founding by Lady Aberdeen, in 1907, of the Women's National Health Association to arouse the women of Ireland to the fact that each year almost 12,000 of the people die of consumption. She organized the tuberculosis exhibition and its success was so great that when the time came for it to start on a tour through Ireland so many towns asked for it that two exhibitions had to be prepared—one for going north and the other south. Up to the present these exhibitions have visited 60 towns and over 700,000 people have attended them—about one-sixth of the population of Ireland. The question may be asked, will all this produce any lasting benefit? Already it has done so. In Dublin a system of home nursing for consumptives has been introduced by means of the cooperation of the medical staffs of the hospitals and the Women's National Health Association. The nurses teach the patients and their friends the ordinary measures for preventing the spread of the disease—the importance of thorough ventilation and cleanliness. They also advise the best dietary and, in many cases, assistance is given in obtaining eggs, milk, meat, etc. Many other towns are following this example. In consequence of the educative effect of the exhibitions guardians of the poor and urban councils are putting up chalets, sheds, etc., in which tuberculous patients can be treated. These sheds are inexpensive, and being erected on the grounds of the hospitals, their cost of keeping is small.

The Supply of Male Nurses.

A want has long existed of a sufficient supply of male trained nurses for cases in which the female nurse is undesirable or objected to by the patient. This want has been filled by the "Army and Navy Nurses Cooperation," which was founded last year with the object of supplying well-trained nurses and sick attendants of good character, at the same time providing employment for retired non commissioned officers and men of the nursing section of the Royal Army Medical Corps and of the Sick Berth Staff of the Navy. In explaining the objects of the institution Sir Frederick Treves said that a large section of the public held that a considerable number of patients who were now nursed by women should be nursed by men. But it was difficult to obtain trustworthy male nurses. They could only come from one course of training—the great naval and military hospitals, where a first-class course of instruction was given. The money earned by the nurses will be handed to them minus a small commission which is so small that it does not pay the working expenses of the institution.

A Coroner on Operations.

Coroner Troutbeck, who has aroused great animosity in the profession by calling in a pathologist in almost all the cases in which he orders a necropsy, and ignoring the local physician, now finds himself in conflict with one of the leaders of the profession, Sir Victor Horsley. Troutbeck held an inquest on a woman who died after the removal of a tumor from the brain, and he summoned this world-famous surgeon who was the operator. Sir Victor Horsley said that the case was such an ordinary one that he could not understand why an inquest was held. The coroner replied that, owing to the advance of surgery, operations were much more frequent than they used to be. Clearly they were, to some extent a cause of deaths and came within the Coroner's Act which made inquests imperative in cases of deaths due to violence. Sir Victor Horsley pointed out that if this were so, 10,000 inquests would have to be held annually. In his remarks to the jury, the coroner said that a considerable proportion of deaths, which in great part were due to operations, were never reported to the coroner. They were certified and, owing to the system of certification, were accepted. As a result, the public were in complete ignorance as to what proportion of deaths were accelerated by operations. This was a serious matter for which a legal remedy was required. He did not intend to let the matter stand. He regarded it as extremely important from the public point of view, and in these matters the coroner represented the public, that such cases should be inquired into. They could leave these questions to no profession, however honored or however skilled. In the case before the court he directed that a proper verdict would be accidental death, if the jury were satisfied that the operation was justifiable and that all due care had been taken. Such a verdict was returned.

BERLIN LETTER.

(*From Our Regular Correspondent.*)

Berlin, June 12, 1908.

The Late Professor Hoffa and the Chair of Orthopedics.

As has been announced in the American press, Professor Hoffa of the Berlin University died some months ago. He was quite closely related to Americans, as he was born in South America. Four years ago, as is well known, he visited America and was much fêted by his American colleagues, which was not to be wondered at considering his charming personality and his remarkable scientific reputation. At the University of Berlin he was the official representative of orthopedic surgery, the second in this position, as his predecessor, the renowned Professor Wolff, was entrusted with the first professorship for this special branch. It created not a little sensation when the faculty, which of course, included the ordinary professors of surgery, made the proposition to the government that the chair (it is not a so-called regular professorship, but merely an "extraordinary" one) of orthopedic surgery should be permitted to lapse and that the orthopedic clinic and polyclinic should be united with one of the two surgical clinics. The proposal aroused opposition both among physicians and with the government which was supported by the public, especially in the Prussian parliament. The government consequently determined not to grant the request of the faculty, but to call a successor to Hoffa. The first attempt to find a suitable man was a failure. Prof. Friedrich Lange in Munich, a very capable man in his profession, refused a call. As usually happens, considerable concessions were made to him by the Bavarian government in order to retain him. He was made a professor in ordinary, i. e., a full member of the faculty, whereas, hitherto he, like Hoffa, had been only a professor extraordinary, and did not belong to the official body of the faculty, thus occupying as it were the position of a professor of the second class. This is the first instance in Germany of the advancement of orthopedic surgery to the dignity of a full professorship. But it will doubtless soon find imitators. It is still uncertain who will be called to Berlin in place of Lange. So far as I know the government has at present in view privat-docent Dr. Wullstein of Halle. The teaching position will not be definitely occupied during the summer but will be held in the interim by a former assistant of Hoffa. Such temporary occupation of ordinary or extraordinary professorships is now more common than formerly in our universities, and more common than should be the case. Even the regular professorship of pharmacology in Bonn, where Professor Binz has retired on reaching the age limit, as well as that in Marburg and in Göttingen are at present temporarily filled.

Cremation in Prussia.

Cremation has hitherto not been permitted in Prussia. There are in Germany only fifteen institutions for burning bodies, so-called crematories, in Hamburg, Heidelberg, Gotha, Jena, etc. At Hagen, in Westphalia, a local society has erected a crematory, but the use of it has been forbidden by the police. As announced in the political press a legal regulation of the practice is to be instituted with a favorable settlement of the question.

The Virchow Monument.

The matter of the Virchow monument has taken on a tragico-comic character. As is well known, the plan was made in 1902, shortly after the death of the great master, to erect a monument in a public square in Berlin. For this purpose a competition was started by the committee in the usual way which resulted in a number of designs for the monument being submitted. The jury, two years ago, awarded the first prize to the design of a talented sculptor, and gave him the right to erect the monument. The design, according to the opinion of many people, does not correspond to the requirements expressed in the original plan of the monument committee, viz.: "That the monument should bear witness to the high esteem in which the German nation held the great investigator, even after his death." The design is not a statue of Virchow himself, but introduces as the chief group, a symbolic representation of the lifework of Virchow, in the form of a struggle between a Herculean giant and a fabulous beast, while on a classic pedestal (beautiful in itself), only a small medallion portrait of Virchow was placed. Energetic opposition was made against this design, especially on the part of the Berlin profession. The *Deutsche medizinische Wochenschrift* first took up the work and protested that for a man like Virchow "who abhorred every mystic and symbolic ambiguity, and who represented in the highest degree the exact investigator of nature, a monument is erected on which the personal and peculiar character to be preserved for posterity sinks to a dwindling little ornament, while elevated to the chief place is a group which symbolizes any fact you please from the struggle of the physical or intellectual giants of the world's history." To these, and other protests, the artist gave so much heed that he enlarged the medallion portrait and placed on the pedestal some reliefs that presented Virchow in his character as teacher. Unfortunately the carrying out of the design could not be hindered by the protest, but now a decided check has been interposed. The emperor, who under certain circumstances must give his consent to the erection of monuments in the public squares of Berlin, has expressed himself against the monument in its present form on similar grounds to those taken by the *Deutsche medizinische Wochenschrift*. One can not agree with all the views of our emperor on art and many innovations in the municipal art of Berlin, lacking in beauty, are referable to the will of the emperor, but in this case we can only be thankful to him that he is willing to protect us from a monument that would in no way be representative of Virchow. What further course the matter will take, whether the monument will be constructed and erected in some private square of the city (perhaps the Rudolph Virchow Hospital) or not, will be known in the near future.

VIENNA LETTER.

(*From Our Regular Correspondent.*)

Vienna, June 10, 1908.

Yellow Phosphorus in Matches.

Since the government has published the essential features of the new bill (to be brought before parliament in the autumn), regulating the use of yellow phosphorus in the manufacture of matches, the Vienna Medical Society has appointed a medical committee to investigate into and report on the conditions prevailing in the trade. About 70 per cent. of all matches made in Austria are made of the yellow phosphorus, the majority of the factories being in Bohemia because of the laxity of the law there. Phosphorus necrosis is not seen as frequently now as it was ten or fifteen years ago, but the records show that in Bohemia about 35 or 40 cases have been received annually for the last decade. Among the lower classes it is not unusual for match-heads to be taken internally as an abortifacient, and many cases of so-called attempted suicides by phosphorus poisoning are really the result of attempted criminal abortion. In Vienna alone the statistics show that 791 females and 80 males have, within the past ten years, attempted to kill themselves by eating match-heads. The mortality is high, no fewer than 340 having succeeded in killing themselves. The result of the committee's investigation was that there seems to be no positive way of preventing phosphorus necrosis except to prohibit the use of yellow phosphorus and substitute the amorphous form of the chemical.

Resignation of Professor Toldt.

Professor Karl Toldt, the famous anatomist, intends to resign his position as director of the second anatomic institute because his research and literary work take all his time. Toldt is the author of many text-books on anatomy, the best known among them being his handbook of anatomy which he wrote in collaboration with Langer. One of his latest books is the "Atlas of Anatomy" which is a departure from the type usually seen. Professor Toldt is now engaged in completing his great work, "Anthropology," and as he is now 68 years old he does not wish to delay his self-appointed task longer.

Medical Council Conflicts with a Sick Benefit Society.

The system of sick-benefit societies (*Krankenkassengesetz*) which makes the physician do much work for small remuneration has not hitherto been successfully fought in Austria because of the lack of proper organization on the part of the profession. The medical council of Vienna, a representative body equipped with certain disciplinary powers, recently ordered that a newly formed sick benefit society of bank clerks be boycotted by medical men. The sick benefit society appealed to the courts on the ground that the existence of sick benefit societies is required by law and the action of the medical council prevented the club from complying with the law. The court upheld the contention of the sick benefit society and its decision can not be appealed from. This occurrence has aroused the profession so that the Society to Promote the Economic Interests of Physicians, which was founded about a year ago, has increased its membership to such an extent that a boycott can now be maintained without fear of any court being able to interfere.

Pharmacology

THE BROADER AIMS OF THE COUNCIL ON PHARMACY AND CHEMISTRY.

TORALD SOLLMANN, M.D.
Member of the Council, Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University.
CLEVELAND, OHIO

(*Continued from page 2146.*)

XV. SOME STUDIES IN BOTTLED PSYCHOTHERAPY

Great is the influence of mind over the body! Evidently, though, its potency of suggestion can be greatly enhanced by the simple process of marketing it in bottles, enhanced to the degree that it controls, not only the body, but also bacteria—and, even ferments. How else can we explain the testimonials of the psychic digestants and psychic antiseptics—when it comes to the psychic cardiac tonics, however, this simple explanation fails.

I. PSYCHIC DIGESTANTS

In The Journal, Feb. 2, 1907, page 434, the Council exposed the absurdity of liquid mixtures of digestive ferments. In the same and succeeding issues, the experimental evidence was quoted and on February 9, the statements of text books were contrasted with the claims made for these preparations. In The Journal, March 16, 1907, the Council reported that Lactopeptine, even in powder form, contains no pancreatic ferment, and only a small amount of pepsin. This result was confirmed by Prof. Charles H. Miller in The Journal, March 23, 1907. Indeed, all this had been anticipated by Prof. Emil Scheffer in 1876.

But profitable falsehoods die hard—which is the reason for again referring to these facts. The reply of the Lactopeptine manufacturers to the Council was the bald assertion that "the ferments referred to exist in the preparation as stated in the formula." Toward the profession, they have adopted a somewhat different tone, implying that the attitude of the Council is mere theory, and that Lactopeptine has "convincingly demonstrated, beyond all question, its practical value." They take pride in contrasting "theory" with "common sense." This is somewhat of a reflection on the acumen of the clinical authors who have condemned these mixtures—Boardman, Reed, Potter, Stevens, Yeo, Butler, Hemmeter, Gilman, Thomson, H. C. Wood, Crofton, Culbreth, and others.

Even if there were this difference between "theory" and "common sense," would it not be well to look for the simplest explanation, before resurrecting or resynthetizing pancreatin from its proteolytic cleavage products by the mysterious vital activity of the intestine? Many patients with digestive disorders doubtless improve under Lactopeptine—*plus* this, that and the other. But then, do they not improve under this, that and the other—*minus* Lactopeptine? I have even heard of digestion being improved by mere attention to diet, without any drugs; I have heard of the (peptic) juice being increased by pleasant tasting substances—and Lactopeptine Elixir does taste pleasant. I have also heard of amulets, and of psychotherapy!

The demonstration of a ferment has thus far been considered as belonging to the domains of chemistry; the promotors of Lactopeptine and the inventors of nucleoenzymes would transfer it to the domain of psychology.

II. PSYCHIC ANTISEPTICS.

What a fine antiseptic odor and taste are possessed by thymol! After comparing the odor and taste of a saturated solution of thymol with a 5 per cent. solution of phenol, or a 1 per cent. solution of corrosive sublimate, could one doubt for a moment which is the most active? Evidently not, for thymol, plus small quantities of boric and benzoic acid, under the name of Listerine, sells at a dollar a bottle. It is really too bad that bacteria can not recognize a superior antiseptic as well as the nose—for, according to the bacteriologic tests, as quoted by Wood, four hundred and ninety-five dollars' worth of Listerine has the antiseptic action of a cent's worth of corrosive sublimate; or fifteen dollar's worth of Listerine equals a cent's worth of carbolic acid.

III. PSYCHIC CARDIAC TONICS.

Thanks to the unique discoveries of the eminent pharmacist of St. Louis, Mr. Sultan, and of the eminent exploiters of alkaloids (and a few other things) the Abbott Alkaloidal Company of Chicago, the treatment of heart-disease has been much simplified. *Cactus grandiflorus*, the famous Mexican plant, contains an inactive active principle, isolated in pure form as an impure extract, which has the most remarkable actions on the human heart. Should the heart be too slow, cactus quickens it; if the heart is too fast, cactus slows it; should the heart be too weak, cactus strengthens it; if the heart is too strong, cactus weakens it; does the heart wobble, cactus steadies it; if the heart is normal, cactus does not meddle with it. No need to make a diagnosis—whatever is wrong or right with the heart, cactus fixes it.

The field of usefulness of this remarkable drug is being constantly extended. As the pellets or granules consist almost entirely of sugar, and are absolutely harmless in doses of one hundred or more (see The Journal, Sept. 21, 1907, page 1023; and March 21, 1908, page 956), they might be useful as an infant food.

A further property of this remarkable drug is that its action is confined to the human heart. This also opens up a new field for the drug in ethnologic research.

N. B.—A definite diagnosis of the cardiac lesion should not be made, since this interferes materially with the efficiency of cactus. Please refer to the title of this paragraph.

(*To be continued.*)

[Contribution from the Chemical Laboratory of the American Medical Association.]

UNOFFICIAL PREPARATIONS OF HYDRASTIS (GOLDEN SEAL).

W. A. Puckner.

In the price-lists issued by most manufacturers of pharmaceutical products there are to be found listed under fluidextracts, the following preparations of golden seal (hydrastis): "Golden seal U. S. P.," "Golden seal, aqueous," "Golden seal, colorless." As the term, "fluidextract," or "fluid extract," designates a class of pharmaceutical preparations of which 1,000 c.c. represent 1,000 gm. of the drug, the several golden seal preparations should be of the same drug strength. It is difficult, therefore, to understand why these preparations should differ so widely in prices. Thus, a recent price-list (Ray Chemical Company) quotes them at $3.60, $2.75, and $1.25 a pint, respectively, in the order named above.

The price lists of some manufacturers shed light on this subject to some extent, at least. Thus H. K. Mulford Co.'s catalogue contains under fluidextracts, "Hydrastis U. S. P.," "Hydrastis, Aqueous (without alcohol)," and "Hydrastis, Colorless (non-alcoholic)," but a foot-note explains that the last preparation is one of those which "differ from fluidextracts in that they are not made 1 gm. to the c.c." So also the price-list of Parke, Davis & Co., which quotes "Golden Seal," "Golden Seal, Aqueous" and "Golden Seal, Colorless," contains an explanatory note which states that "Golden Seal, Colorless" does not represent the crude drug minim for grain.

On the other hand, the price-list of Hance Bros. & White contains an explanatory note which leads to the inference that their golden seal preparations are all of the same strength, thus:

> "The Golden Seal used in our preparations is assayed to the standard of 2 per cent. white alkaloid Hydrastin, this being the alkaloid which produces the characteristic physiologic effects.
>
> "We list three Fluid Extracts, Golden Seal U. S. P., Golden Seal, Aqueous, and Golden Seal, Colorless. Fluid Extract Golden Seal, U. S. P., contains resinous matter and will not make a clear

solution with water Fluid Extract Golden Seal, Colorless contains only the white alkaloid Hydrastine in an aqueous solution and is especially prepared for medication of the genito-urinary mucous membrane It makes clear solutions with water and does not stain linen"

Yet the preparations are offered, respectively, at $4 50, $3 75, and $3 per pint.

Evidently, therefore, there is something radically wrong in the system which lists under fluidextracts, Golden Seal, Aqueous and Golden Seal, Colorless. To investigate the matter further, the products of a number of manufacturers were purchased in the open market and examined.

GOLDEN SEAL, AQUEOUS.

The table below gives the descriptions as they appear on the labels of the products supplied by the manufacturers and also the percentage of the alkaloid hydrastin which they were found to contain when examined by the process of the U. S. Pharmacopeia and by a modification of the official method (Method B). The results of the assays by the latter method, as has been explained elsewhere,[1] are somewhat higher than those obtained by the official method. The latter determinations were made, and the results are recorded only as a verification of the values obtained by the first, the official method. It should be remembered that the official strength of fluidextract of hydrastis is 2 gm alkaloid to the 100 c c, whereas, the preparations mentioned below varied from 0 58 to 1.79 gm

GOLDEN SEAL AQUEOUS

No	Firm.	Title on label.	Claims made.	Grams of hydrastin in 100 c c of preparation By U S P. Method	By Method B
1	Hance Bros and White	"Fluid Extract Golden Seal aq"	"The irritating resin of golden seal is eliminated and only the alkaloid retained"	1 43	1 49
2.	Eli Lilly & Co.	"Fluid Golden Seal (Non alcoholic)."	"The resin and other inert matter is eliminated while the hydrastin and berberin are retained in natural combination, 1 25 gm hydrastin in 100 c c"	1 09	1 16
3	H K Mulford Co	"Fluid Extract of Hydrastis aqueous"	"Represents the medicinal properties of hydrastis but excludes the resinous extractive"	0 58	0 64
4	Parke, Davis & Co	"Fluid Golden Seal, Aqueous"	"Represents the medicinal properties of hydrastis The resinous extractive has been excluded" "Standard 1 per cent hydrastin"	0 93	0 95
5	Ray Chemical Co	"Ray's Fluid Ext Golden Seal non alcoholic"	"Represents the medicinal properties of hydrastis The resinous extractive has been excluded"	0 77	0 82
6	Schieffelin & Co	"Aqueous Fluid Extract of Hydrastis"	No statement" except "contains no alcohol"	1 31	1 35
7.	Sharp & Dohme	"Fld Extr Golden Seal Aqueous"	"Each cubic centimeter represents 1 gram of Golden Seal"	1 50	1 62
8	Frederick Stearns & Co	"Fluid Extract Hydrastis Aqueous"	"No claims made	1 79	1 79
9	Truax Greene & Co	"Fld Ext Golden Seal without alcohol"	"Contains all the native principles of the drug except the inert gummy and resinous matter . ."	1 04	1 10
10	Wm Warner & Co	"Fluidextract Golden Seal without alcohol	No claims made	1 26	1 35

The above table shows that, with one exception (No 8), the "non-alcoholic," "aqueous" hydrastis preparations examined should not be designated as fluidextracts since they do not contain the amount of the alkaloid hydrastin which the Pharmacopeia directs for fluidextract of hydrastis (2 per cent.). Only one product, that of Stearns, approached the alkaloidal strength the official fluidextract. In reply to an inquiry, Frederick Stearns & Co. claimed that the preparation was made in April, 1907, and at that time assayed exactly 2 per cent. hydrastin.

Two firms, Eli Lilly & Co, and Parke, Davis & Co., do not use, on the label, the word "fluidextract," but instead, call their preparations, respectively, "Fluid Golden Seal, Non Alcoholic," and "Fluid Golden Seal, Aqueous." These firms also state the amount of alkaloid which these preparations contain, viz, 1 25 per cent, and 1 per cent., respectively, and the examination confirms these claims in a general way.

The results of the analyses were submitted to the several firms interested who were requested to state how these results agreed with those obtained by their own chemists The replies received, indicate that either the preparation is made and sold without control of its alkaloidal strength or, if assayed, no attempt is made to meet the official standard for fluidextract of hydrastis.

In brief, this examination demonstrates that few of the so called "non alcoholic" or "aqueous" fluidextracts of golden seal, deserve the title, "Fluidextract." It also indicates that, in addition to the claim that the inert constituents have been removed, equal prominence should be given to the fact that, to a large extent, the chief active constituent also has been removed. The replies of the manufacturers generally indicate that being an unofficial preparation, little attention is paid to its strength (something on the order of the "eggs good enough for custard," of Mr. Peck's illustrious son); but they also show a willingness to improve the quality of the product or to label it properly.

GOLDEN SEAL, COLORLESS.

On the labels of the trade packages of the so called "Golden Seal, Colorless" preparations, the following descriptions appear

Hance Bros & White "Liquid Golden Seal, Colorless" "One fluidounce represents one and one quarter grains (0 081 gm) hydrastin"
"This preparation is simply a solution of the White Alkaloid of Hydrastis Canadensis in approximately the proportion in which it exists in a prime quality of the drug—twenty grains to the pound—and without the addition of any ingredient intended to increase its action"

Eli Lilly & Co: "Liquor Hydrastin"
"This preparation, frequently called 'Colorless Hydrastis,' contains the colorless medicinal principles of Golden Seal"

H K Mulford Co: "Fluid Hydrastis (Colorless)"
"Each pint of the fluid contains 20 grains of white alkaloid, the only valuable constituent of Hydrastis"

Parke Davis & Co · "Fluid Golden Seal, Colorless"
"Each fluidounce of this fluid contains 1¼ grains of Hydrastin, the white alkaloid of Hydrastis (Golden Seal)."

Ray Chemical Co . "Ray's Fluid Extract Golden Seal (Colorless)"

Sharp & Dohme "Fluid Golden Seal, Colorless"
"Each pint contains 20 grains Hydrastin White Alkaloid, the principal and most valuable constituent of Golden Seal"

F Stearns & Co: "Fluid Golden Seal (Colorless)"
"Each fluidounce of this preparation contains 1¼ grains of Hydrastin (White Alkaloid), to which, recent investigations have shown, the valuable properties of Golden Seal (Hydrastis) are due"

Truax, Greene & Co · "Liquid Hydrastin"
"Fluid Golden Seal, Colorless"
"One pint of this solution contains an amount of the 'White Alkaloid' Hydrastin equivalent to that contained in one pound of fresh Golden Seal root of average quality"

H K Wampole & Co "Fluidextract Golden Seal, Colorless"
"Each pint contains, in a non alcoholic menstruum Hydrastin, 20 grains"

Wm R Warner & Co · "Fluidextract Golden Seal, Colorless"
"Each pint contains 20 grains Hydrastin"

The above shows that only a few firms use the word "fluid extract" on the label; nor, with one or two exceptions, is any attempts made to make it appear that the preparation approaches fluidextracts in strength. In general, the labels show that they are weak solutions of salts of hydrastin. While the fluidextract of hydrastis contains 2 per cent of alkaloid, these preparations contain less than 0 3 per cent.

---

[1] Pharmaceutical Review, May, 1908, p 132

[2] In Schieffelin & Co's prices current of March 30 1907 it is stated that "Hydrastis aqueous" is standardized to U S P strength On corresponding with this firm it appeared that the sample analyzed was of old stock, of which Schieffelin & Co said "None of the old stock should have been sent out subsequently to the issuing of the price list, and we regret to find that a few liters of what we had on hand were sent out Therefore, we have no doubt that your analytic results are correct and we can only express our mortification that our oversight should have put us in this position" Analysis of a new specimen submitted showed the amount of alkaloid present as represented—that is of standard U S P. strength

The statement made by Truax, Greene & Co. that one pint contains an amount of hydrastin equivalent to that contained in one pint of fresh golden seal root is, to say the least, misleading. Casual reading gives the impression that this preparation contains an amount of alkaloid equivalent to that prescribed for the official fluid extract. The word, "fresh," however, which probably will, and perhaps is intended to escape the reader, is of considerable importance in this case. According to J. U. Lloyd[3] and Alice Henkel[4] every 100 pounds of fresh golden seal, when dried for the market, yields only 28 to 30 pounds.

Since the U. S. Pharmacopeia requires that golden seal contain 2.5 per cent. hydrastin, the "fresh" drug should contain only 0.6 per cent. The preparation of Truax, Greene & Co., however, does not contain even this amount; examination[5] indicating that it contains less than 0.25 per cent. of hydrastin. To a considerable extent, the same criticism applies to the product of Hance Bros. & White, who state that the alkaloid is contained in their liquid Golden Seal, Colorless, "approximately in the proportion in which it exists in a prime quality of the drug." This is followed by the acknowledgment that it contains 20 grains to the pound. Hance Bros. & White apparently feel confident that physicians are quite unfamiliar with the alkaloidal content of drugs!

THERAPEUTIC INDICATIONS.

In conclusion, the following statements taken from the label for these preparations show the extent to which some manufacturers go in their desire to tell physicians (and others?) the various uses to which this remedy may be put:

> "It is indicated in atonic dyspepsia, gastritis, and in the treatment of catarrhal affections of the mucous surfaces; also a wash in conjunctivitis and an injection in gonorrhea, vaginal leucorrhea and inflammation and ulceration of the mucous lining of the bladder. It is free from all staining properties. When used as a wash or injection, it should be diluted with from four to twelve times its volume of water." (Hance Bros. & White.)
>
> "Non-irritant, permanent, will not stain, contains no alcohol. Will be found useful wherever Golden Seal is indicated."
>
> "Medicinal Uses: It is recommended for various inflammatory and catarrhal conditions of mucous membranes; as an injection in gonorrhea, leucorrhea, and other catarrhal affections of the genitourinary tract; also in inflammatory conditions of the nasal and air passages. Internally is employed in fermentative dyspepsia, malarial troubles, biliousness, gastric catarrh, gastritis, etc. May also be used in combinations, according to the discretion of the prescribing physician." (Stearns & Co.)

The examination demonstrates that these unofficial preparations, while listed and sold more or less directly under the titles of fluidextracts, do not comply with the standard adopted for the official fluidextract of golden seal; the results may serve as a suggestion to physicians to make some attempt to learn the composition of unofficial remedies. The analyses emphasize the fact that, with hydrastis as with many other drugs, as soon as the physician leaves the official preparations he is dealing with unknown quantities.

RESEARCH LABORATORIES OF MANUFACTURING PHARMACISTS.

Valuable Work in Standardizing and Investigating Drugs.

The advance of pharmacy and therapeutics has been due in a considerable measure to the enterprise of certain manufacturing pharmacists who have conducted research laboratories from which genuine scientific discoveries have emanated. In this work the American pharmacist has not been behind his continental brother. It is gratifying to observe that this effort to assist scientific progress still continues. Two contributions in the *American Journal of Pharmacy* (January and March, 1908), are striking examples of the practical value of such work. The first emanates from the biologic laboratories of Parke, Davis & Co., and consists of a study of *Cannabis sativa*, grown in the United States and Mexico (*Cannabis Americana*), as compared with *Cannabis sativa* of the East Indies (*Cannabis Indica*). It is generally believed that American hemp is practically worthless for therapeutic purposes and that one must employ the true cannabis from India in order to obtain physiologic activity. In order to test the value of American grown hemp, Drs. E. M. Houghton and H. C. Hamilton compared the two drugs by administering the extract in a standard dose to especially selected dogs. They conclude that *Cannabis sativa*, when grown in various localities of the United States and Mexico is fully as active as the best imported Indian-grown *Cannabis sativa*.

The second contribution is an attempt to solve the problem of the standardization of the preparations of digitalis. For this purpose two different methods have long had their special advocates, some championing the chemical method, and others concluding that, because the essential active principle of digitalis is not fully known, nothing could be expected from the chemical method and that the method of physiologic testing must be resorted to. Dr. E. D. Reed and C. E. Vanderkleed, working in the research laboratory of the H. K. Mulford Company, have attempted to compare and combine the two methods. The question of physiologic standardization of digitalis, which is described by Dr. Reed, has resolved itself into the specific action of the drug on the heart of the frog. Frogs were treated with digitalis in varying quantities, and that amount of digitalis which would kill a frog of a definite weight, leaving its heart in systole, was considered to be an index of the physiologic activity of the preparation. This method, however, is considered by Dr. Reed to be unsafe since it is, after all, only a toxic effect and amounts to nothing more than determining the lethal dose. Reed uses, instead, the lethal dose for a guinea-pig and adopts, as a standard, the amount which will kill a guinea-pig of 240 grams weight in from 1½ to 2 hours, and he uses this amount for comparison with the chemical method of testing based on the amount of digitoxin in the drugs.

Vanderkleed, in discussing the objections to the chemical method of standardization admits that it is not proved that digitoxin represents the therapeutic activity of digitalis in its entirety. He maintains, however, that it may properly be taken as a guide for standardization if it can be shown that the physiologic activity runs parallel to the amount of digitoxin so that it may afford a reliable means of approximate estimation. He cites other cases in which it has been agreed to use the amount of an ingredient which is not the sole active principle. Thus, nux vomica is estimated by the amount of strychnin which it contains, although strychnin forms only one of the constituents to which nux vomica owes its activity. Acting on this principle he endeavored to ascertain the relation between the amount of digitoxin and the activity of the digitalis as determined by physiologic tests. The results showed that the relative activity could be estimated very closely from the amount of digitoxin, and it is only necessary to fix a standard of digitoxin corresponding to the physiologic unit in order to assay the drug satisfactorily by chemical means.

Vanderkleed made some interesting experiments to determine the rate of deterioration of liquid preparations of digitalis. Watery solutions of digitoxin are found to lose their activity rapidly so that the only stable preparations are hydroalcoholic or those in which a part of the alcohol has been replaced by glycerin. Even the fluid extract deteriorates, according to his experiments, under ordinary trade conditions, at the rate of about 11 per cent. a year.

The standardization of drugs which are to be depended on for definite physiologic effects is an essential for accurate clinical observation and effective therapeutics and should be demanded where possible. Every effort to extend our knowledge in this respect deserves the hearty support of the medical profession. Work of this sort that tends to make more effective the remedies we already have is much more to the credit of the manufacturing pharmacist, and will be more appreciated by the medical profession than the multiplication of formulas of the "shot-gun" order—already too numerous. It is to be regretted that even the firms which we have just had occasion to mention with praise have not always been willing to forego the temporary profit accruing from proprietary mixtures which have little to recommend them. It is to be hoped that the approval of their scientific efforts will lead them to give these efforts the greater emphasis and to leave the marketing of nostrums to the pseudo pharmacal and chemical concerns which have too long humbugged our profession and disgraced American medicine and pharmacy.

Analysis of Nostrums in North Dakota.

It is gratifying to note that the officials of some of the state health boards have realized the true scope and responsibility of the work placed in their hands and appreciate the great injury to public health from the fraudulent manner in which many medicines are advertised and sold. In the eighteenth annual report of the North Dakota Agricultural Experiment Station, the food commissioner, E. F. Ladd, and the pharmacist L. A. Brown, call attention to the evils arising in connection with the "patent medicine" business. Mr. Ladd says: "The more I have had occasion to look into the subject of 'patent medicines' and their use, the more fully I become convinced of the great fraud that is being practiced. Among the 'patent medicines' there are some possessed of merit, but the greater proportion of those now sold are nothing more than worthless products, often dope.'" He also quotes a drug journal to show the attitude of others with regard to some of these products "which claim to be ethical and, therefore, are supposed to be recognized and used under the direction of physicians but which in reality, seldom are recommended by physicians of standing."

Mr. Ladd makes the further comment: "By reference to the report of Professor Brown given further on one will see something of the character of 'patent medicines' which have been sold in this state and have thus far been under examination. Their worthlessness in many cases is clearly indicated. They are often so prepared as to deceive and mislead and make victims of those who use the products. That there is necessity for a more stringent law than any which we now have is clearly indicated, and I can fully endorse the report of Mr. O. C. Beale who was commissioned by the Australian government to make an investigation of the nostrums sold as 'patent' and proprietary medicines in all English speaking countries."

Professor Brown's report shows a large amount of good work accomplished during the year. A long list of proprietaries containing cocain is published. Vin Mariani is in this list and receives an exposure occupying over two pages and leading to the conclusion that whatever the claims made by the manufacturers "according to our analysis of samples of Vin Mariani it *does* contain cocain, and regardless of whether its presence is due to coca leaves or not, it constitutes it a cocain preparation." Evidently hair spliting distinctions are not very popular at the North Dakota Agricultural Experiment Station.

The results of the analysis of some "dyspepsia remedies" are very interesting. The report states: "Only a few preparations of this nature have been analyzed in this laboratory owing to a limited amount of time and help trained in drug analysis, but enough has been done here and elsewhere to arouse in our minds the suspicion that there are very few preparations put up as aids to digestion that have any efficacy whatever." Among the preparations analyzed were Vigmi and Malt Papaya, Borscherdt's. The first showed no digestive power and the second a slight action on starch, but none on albumin. It is suggested that in the combination of diastase and papayotin in the second preparation the two ferments mutually destroy each other as has been shown to be the case with mixtures which contain both pepsin and pancreatin in solution.

It is to be hoped that we may have more investigations of similar nature by the responsible boards which are equipped to do work in this field. One advantage of work done under public authority not connected with the medical profession is that the suspicion of medical bias is removed and the advice given in such reports as these ought to be of immense value to the people to whom they appeal and who are liable to be misled by the specious advertisements of nostrums which are both an injury to health and a fraud on the purse.

Correspondence

Priority in Regard to Patellar Synovial Fringes.

NEW YORK, June 18, 1908.

To the Editor:—The rapid increase of years renders it hardly probable that I can accomplish much further work of novelty or interest in surgery. Hence, I may be pardoned for calling attention to what I have done in the past in connection with a lesion presented in an able form by Dr. Abbott of Portland in THE JOURNAL, May 23, p. 1675. He ascribes the recognition and the requisite surgical treatment of an unusual form of joint locking due to a duplication of the synovial membrane on the under surface of the patella to Dr. Goldthwait, who operated for this condition in 1902. I venture to state that in the *Medical Record* of July 16, 1892, it will be found that I called attention to this lesion and, by a similar procedure to that used by Dr. Abbott, removed the projecting fold in two instances, though I did not then, nor do I now claim to be the originator of the operation or the discoverer of the disease. It was only recognized as a unique affection.

R. F. WEIR.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Sentences for Charlatans in the German Courts.

The last number of the *Gesundheitslehrer,* the official organ of the Antiquackery Society, mentions nearly 20 suits brought against quacks, the penalty ranging from fines of $5 to $75 and imprisonment for from two weeks to three years. Among them is L. Bauer, of "antidiabeticum" fame, this being the eighth suit that has been brought against him. One Witte was given a year's imprisonment for treating a woman with cancer and promising to cure her. It says of another, a shoemaker, that he grew tired of working on shoes and determined to take charge of the health of his fellowmen, "and of course he found people at once to trust their health in his hands." He treated a lad with a tuberculous suppurating process in the pelvis and promised his father a cure in six weeks. He applied a plaster cast, never cleaned, but charged $2.50 for each inspection. After the boy's death suit was brought and he was condemned to two weeks of prison, the fourth penalty for the same practices.

Systematic Organization in Kansas City.

The Jackson County (Missouri) Medical Society has taken up systematic methods of organization, following the plan of the Chicago, Philadelphia and St. Louis medical societies, and dividing the county into districts. A representative from each district has been appointed on the general organization committee, thus forming an organization committee of twenty-seven, one for each ward in Kansas City and Independence, and one for each township in the surrounding country. The secretary, Dr. E. L. Stewart, has begun the compilation of a card index of all the physicians of the county, and is endeavoring to obtain personal data regarding all members of the profession in the county. Without doubt, the work in Jackson County will be as productive of good results as that in the other large cities which have adopted this method.

Local Regulation of Nostrums.

Following the movement on the part of the *national* and state governments for the regulation of the sale of dangerous and fraudulent medical preparations, a number of cities have passed similar local ordinances. Such an ordinance was adopted recently by the council of Huntington, Ind. This example is being followed by a number of other cities in the state. Logansport has just passed an ordinance providing that any itinerant physician or other traveling person desir ing to sell any medicine, drug or remedy for use in curing or healing diseases must obtain a license and pay to the city treasurer $50 for each day he intends to remain in the city. Such an ordinance is in every way to be commended, and it is to be hoped that other cities will take the same action. It might be advisable to consider an additional clause prohibiting the sale to the public of any medicinal preparation which had not been examined by the State Board of Health and pronounced safe for public use.

Medical Defense in Wisconsin.

The State Medical Society of Wisconsin, at its annual meeting in 1907, adopted a plan of medical defense which has now been in operation for nearly a year. The *Wisconsin Medical Journal*, May, 1908, contains extracts from reports received from many of the counties, showing that in almost every instance the system has met with general favor and that the members are much pleased with the plan. In only a single county was there any definite opposition, and in this county the year has shown a substantial gain in membership. So far as reported, there has been no loss in membership in any county on account of the adoption of this feature, and this experience is in accordance with that of other state associations which have adopted it.

The best thing about this plan of mutual protection is that, without exception, it has resulted in eliminating those cases which are without justification and which had been incited by lawyers for mercenary reasons. Cooperative defense has made systematic exploitation of the medical profession not only unprofitable, but inadvisable and impossible. The few cases which have some possible justification are easily adjusted and settled. The principle of cooperative medical defense as a function of state society activity seems now to be well established, and it is to be hoped that many other state associations will take up this matter and carefully consider it.

Local Physicians' Club.

For over ten years the physicians of New Kensington, Pa., have maintained a local club, composed of the physicians of the city, who are members of the Westmoreland County Medical Society. The club at present includes fourteen out of the fifteen physicians of New Kensington. Weekly meetings are held, which are always well attended. The club has recently taken up the postgraduate course of study with gratifying results. It has its own club room, and hopes in a short time to have the nucleus of a common medical library. The best of feeling and the heartiest cooperation prevails among the local physicians, due principally to their constant association and frequent meetings together.

This organization is an illustration of the necessity in some of the counties of a smaller organization inside the county society for purposes of mutual benefit. In many of the larger and more populous counties, it is practically impossible for all the physicians to assemble oftener than once a month, or, on account of the geographical conditions or railroad arrangements, it is exceedingly difficult for all the physicians of the county to meet in one place. These difficulties have been solved in some counties by the organization of branch or district societies, subordinate to the county society; in others, by the organization of local clubs, which are auxiliary to and limited to members of the county society.

While any tendency toward disintegration or drifting away from the county plan of organization should be carefully avoided, yet such local organizations when properly conducted are an additional incentive to membership in the county society, and can often be of benefit to its members in a way not possible to the larger organization.

The Chicago Medical Society and Its Active Work.

The *Bulletin of the Chicago Medical Society*, June 20, contains the report of the annual meeting of that body held on June 17, which shows in a striking manner the range of work covered by this society, as well as the possibilities of medical organization in the large cities.

Seven years ago the Chicago Medical Society was a single body of about 900 nominal members, confining its work almost entirely to the reading and discussion of scientific papers. To-day it is a highly specialized organization, having 2,259 actual members of the main society, twelve affiliated special societies and fourteen district branches. Instead of one meeting a week, there is now an average of 32 medical society meetings every month in Cook County. Not only has the organization gained in membership, but its practical usefulness has largely increased. A council, composed of delegates from the different component parts of the organization, meets each month and transacts all the business for the society. At the annual meeting, reports were made by the secretary of each of the fourteen branches and of the twelve affiliated societies, as well as by the following committees: Membership, medicolegal, ethical relations, organization, propaganda, patent nostrums, business bureau, contract practice, abuse of medical charities, affiliated societies, educational campaign and constitution and by-laws.

The medicolegal committee reported that in the three years of its existence it had not lost a single case. The report of the organization committee showed that 454 applications had been taken during the year, of which 303 had been accepted up to the date of report, and that in the last six years there had been added to the society 1,460 new members. The committee on propaganda reported that 22 public lectures had been given in the Public Library Building during the year, with an average attendance of 140 and a maximum attendance of 350, and that more interest had been exhibited by the public in these lectures during the past year than at any previous time. The committee on business bureau reported that this institution had been in existence for five months and had collected a total of $6,298 for members of the society, earning in commissions for the society $1.279, and that 391 members were now sending their bills to the bureau for collection. The committee on abuse of medical charities reported that during the past year an organization of the free dispensaries of the city had been effected, comprising 27 of these institutions, and that plans were being developed to prevent the exploitation of the medical profession through the misuse of these establishments for the relief of the worthy poor. The educational campaign committee reported that seven meetings had been held during the year between local physicians and druggists for the solution of the proprietary medicine and nostrum situation. The report of the secretary showed the largest annual increase in the history of the society. Thirty-one meetings of the main society were held during the year with an average attendance of 185.

The Chicago Medical Society was one of the first of the large city organizations to realize the trend of the reorganization movement and to appreciate its possibilities. An enormous amount of hard work has been done by its officers and members in the past six years, with the result that it stands to-day as the largest and best organized local medical society in the world.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR. JOHN H. BLACKBURN, DIRECTOR.
BOWLING GREEN, KENTUCKY.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month.

THIRD WEEKLY MEETING.

Cholelithiasis.

Etiology.

Classification of gallstones, chief constituents. Origin of cholesterin and bilirubin—calcium, changes necessary to their production. Effects of chemical and bacterial irritants, organisms usually found in bile, in gallstones. Effect of stasis of bile. Entrance of micro-organisms (a) by common duct, (b) by blood current, from portal vein. Age and sex. Pregnancy, sedentary life, typhoid fever. Incidence.

Symptoms.

Obstruction of Common Duct: Symptoms of cholangitis. Mechanical effects. Jaundice; intensity, duration. Itching.

Pain Temperature chills, "Charcot's intermittent fever Gastric disturbances Physical examination Symptoms of suppurative or ulcerative cholangitis Association of pancreatitis

Obstruction of Cystic Duct Pain, jaundice, tenderness, gastric and intestinal disturbances, presence of tumor. Sequelæ empyema, atrophy or calcification of gall bladder

Remote Effects (a) Stricture of the duct, (b) intestinal obstruction, (c) fistulas

Amyloid Disease of the Liver.

Etiology Microbic origin of amyloid degeneration, its occurrence in the body Sequel of chronic suppurations, necrosis of bones, tuberculosis, pyelitis, syphilis, blood dyscrasias Tests for amyloid material

Symptoms· General condition, gastrointestinal symptoms mental derangements pain, urine Physical examination

---

Miscellany

Acidosis in Pregnancy—J B Leathes (*Proceedings of the Royal Society of Medicine*, March 1908), refers to 'three groups of papers in which, in Germany and America attention has been called to the significance of the high proportion of the excreted nitrogen that may take the form of ammonia salts in the urine during pregnancy" These groups are represented, respectively, by the papers of Zweifel (*Arch f Gynak*, 1904, lxxii, 1· 1906, lxxvi, 536), Williams (*Johns Hopkins Hosp Bull*, 1906 xvii, 71), and Ewing and Wolf (*Am Jour Obst*, 1907, lv) Zweifel's consideration of eighteen successive cases of eclampsia lead him to the conclusion that 'the acid is produced in the child and causes poisoning of the mother, and is not produced in the mother as a result, for instance of the fits" Williams regards three remarkable cases (abstracted in this article) of severe vomiting in pregnancy as 'cases of toxemic vomiting allied to yellow atrophy, and this latter as a fulminating variety of the same disorder Other cases of severe vomiting in pregnancy, in which the ammonia coefficient is normal may be recognized by that sign as of a comparatively innocent type—cases of neurotic or it may be, reflex vomiting" The cases of Ewing and Wolf, which Leathes regards as affording the fullest and most valuable set of analyses of the urine in pregnancy," are divided into six groups These are analyzed and from a consideration of them Leathes says "The two types of abnormality are fairly distinct One is characterized by severe vomiting in the early months with high ammonia coefficients and generally large amounts of undetermined nitrogenous substances, but no renal affection The cases described by Williams emphasize the gravity of this condition, described as toxemic vomiting and with their very high ammonia coefficients give further significance to this abnormality of the urine The other is an affection of the later months, in which the vomiting is secondary to renal complications, a pre eclamptic condition in which the urine does not commonly have a particularly high ammonia coefficient, though the undetermined nitrogen appears to be very abundant" Leathes then raises the question "How far are these abnormalities in the urine diagnostic indications of the gravity of the disorder? Do they lie at the root of the malady, as early fundamental symptoms of a disturbance of metabolism of which, it may be, yellow atrophy or conditions of that order of gravity on the one hand and eclampsia on the other, may be merely the final climax?" He discusses the subject and concludes that so far as the ammonia figures in the disorders of pregnancy are concerned, before it can be safely maintained that these high figures are a sign in themselves of a toxemia that is likely to prove fatal unless the most active measures be taken, it is necessary to prove that they are not sufficiently accounted for by some of the attendant circumstances of the patient's condition the low nitrogen content of the absorbed food, the imperfect nutrition due to the incessant vomiting, the loss of alkali in the vomit, aggravated possibly by the requirements of the fetus The facts that the high figures may occur without any symptom of general disturbance (Ewing and Wolf's cases, 3 to 6), and that profound disturbance may coexist with normal figures (*ibid*, Cases 10 and 12, the latter fatal), are difficult to reconcile with such a view In some of the recorded cases acetone is mentioned as having been detected, which is no more than could be expected, and, therefore, the acids associated with acetone were probably present in sufficient quantity to account for some of the excess of ammonia The valuable data contained in Ewing and Wolf's paper, and the stray observations outside it, point to the necessity of decisive experimental work before their pathologic significance can be positively defined The other abnormality of the urine, the large output of unknown substances containing nitrogen, is more striking and more suggestive, for this does not appear among the results of mere starvation, as the figures given by Cathcart (*Jour. Physiol*, London, 1907, xxxv, 500) show The only substances that have been detected giving rise to variations in the nitrogen in this category are amido acids, and though, of course, this does not warrant a prejudice as to the meaning of the figures in disorders of pregnancy, if the presence of amido acids in abnormal amounts were proved, it is possible that some of the abnormal ammonia figures might be explained in that way, and that the tendency to associate the abnormality of the urine with disturbance of hepatic functions, and to regard it with suspicion as a sign of danger from that quarter, would be strengthened But the author concludes that further definite work on this subject is required before any attempts at interpretation of the phenomena are permissible

Treatment of Tuberculous Glandular Disease—A Robin states that there is only one treatment for tuberculous adenitis, namely, medical treatment based on the following rules 1 Treatment should be both local and general 2 Local treatment should include local treatment of all the cavities with which the diseased glands are connected 3 The glandular lesions may heal spontaneously under climatic or medical aid 4 When tuberculous adenitis does not heal, it requires further measures, but not surgical ones 5 Surgical intervention does not protect against recurrence, it exposes to generalization, and it leaves disfigurement 6 The treatment should leave no disfiguring traces 7. General treatment includes hygiene as for pulmonary tuberculosis, nutritious food, little meat but plenty of vegetable albumin, especially gluten, and articles like gelatin which oxidize easily and are thus consumed in the place of the tissues, tonics, and hydromineral treatment He combats the "demineralization" with a powder each day containing.

℞	gm		
Magnesii carbonatis	10		gr iss
Calcii carbonatis	25		gr iv
Tribasic calcii phosphatis	25	or	gr iv
Calcii fluoridi	01		gr 1/6
Sacchari	1		gr xv

He considers the seashore dangerous for children requiring or having passed through an operation, or when there is a prospect of acute exacerbation or when there is a tuberculous lesion in the lungs, pleura or abdomen or vague pains in the legs suggesting impending meningitis, or neuralgia He applies locally to the glands compresses soaked in a solution made as follows

℞		gm		
Calcii chloridi		300		℥x
Sodii chloridi				
Magnesii chloridi			or	
Potassii chloridi	āā	15		℥ss
Water		1,000		℥xxxii

He also advises a disinfectant spray to combat any possible tracheobronchial adenitis, with. further, lavage of the nose, throat and ears He regards the care of the mouth as very important, and he has the teeth brushed three times a day with a disinfecting powder containing calcium carbonate, soap and camphor, followed by a beta napthol gargle His lecture on the subject was published in the *Annales de Méd et Chir. infant*, March 15, 1908

Prevention of Plague—The present epidemic of plague is remarkable for its geographic extent although it has not reached alarming proportions in any country except India. In 1894 there was but one country, China, affected; in 1907, there were 51 in which it had gained a foothold. It appeared in India in 1896 and in 1907 attacked 1,400,000 people in that country with a mortality of 1,200,000. *Public Health Reports* (U. S. P. H. & M. H. S., May 29, 1908) details the measures to be taken for preventing the disease. The subject is divided into (a) measures to prevent the introduction of the plague into a community, (b) the proper treatment of a community into which the disease has found an entrance. Precautions to prevent the entrance of the disease are directed (1) Against infected persons, (2) against rats. Quarantine measures should be especially directed to the discovery and detention of ambulant cases and cases of pneumonic plague. The thermometer should be thoroughly used to detect infectious disease among the crew and passengers of incoming vessels. C. S. Braddock recommends the use of coal oil about the shoes, stockings and leggings to prevent the access of infected fleas. A similar application should be made to floors and furniture after disinfection. Warning should be given against petting stray dogs which may harbor infected fleas. The period of incubation is seven days and the period of quarantine should be sufficient to complete a period of seven days from the last time of exposure to infection. Precautions should be instituted to prevent rats from coming ashore, infected vessels being unloaded by lighters at a distance (one-fourth to one-third of a mile) from which it will be impossible for rats to swim to the shore. The precautions against rats should be extended to fleas also. Fumigation of incoming vessels should be complete and provision should be made for the periodic fumigation of vessels trading with infected ports.

When plague has made its appearance in a locality an active campaign against rats should be instituted, these rodents being shut off from houses and food as completely as possible, all garbage being quickly collected and burned, and the rats poisoned or trapped. Arsenic, phosphorus paste and carbonate of baryta are recommended as poisons. The kind of poison and the mode of displaying it should be frequently changed. Patients with plague should be removed to a rat-proof hospital and suspects should be segregated long enough to cover the incubation period.

Dead rats shoud be carefully examined and all precautions taken to prevent rats going from an infected city to vessels lying in the harbor. The ropes connecting the vessel with the wharf should be provided with rat funnels and for a distance of two feet somewhere between the wharf and the opening of the funnels the line should be copiously tarred. Rags should be sterilized or destroyed.

Serious Epidemic of Sore Throat Traced to Milk.—A peculiar streptococcus was found by Ustvedt in the throat in 146 cases and by others also in large numbers, similar to the bacteriologic findings in the mastitis of a cow in the dairy from which the families involved purchased their milk. The symptoms included high fever and enlargement of the glands, tonsillitis with or without an easily detached false membrane, although the aspect of the throat was generally scarlatinal. Gastrointestinal disturbances were rare. All the sick had used unboiled milk from this dairy near Christiania. Only one-third of the patients were children. About 208 sickened between March 3 and 7. In most cases the affection subsided in a week, but in the others complications were numerous, including otitis media, ulceration in the tonsils and vicinity, glossitis with the tongue so swollen that it protruded from the mouth, erysipelas, esophagitis, albuminuria, acute rheumatism or pericarditis; in one case hemorrhagic nephritis, in another thrombosis; one woman had febrile gastroenteritis for several days two days after drinking four glasses of the milk. In one group of 53 patients the remissions and exacerbations of the fever and the glandular disturbances and local complications kept up the trouble in 47 for one or two weeks, for three weeks in 3 and from four to nine weeks in the others. The 6 fatal cases were in infants or the aged except one woman of 47, apparently convalescing three weeks after the first symptoms; pain suddenly developed in the muscles and the temperature rose constantly with death the fifth day from edema of the lungs. The local medical society had a symposium on the "milk epidemic" May 13, reported in the *Norsk Magazin for Lægevidenskaben*, June. The epidemic was remarkable for its virulence in man while in the cow it caused merely a mild local affection. The total number of cases in regard to which the authorities were notified was 548, the notices being sent in by 29 physicians.

Health-Education League Pamphlets.—We have received a package of the booklets of the Health Education series published by the Health Education League of Boston. These little pamphlets present the first necessary element for all efficient food whether of mind or body: they are attractive. While all attractive things may not be desirable and many even may be prejudicial, there can be no question that attractiveness of form vastly increases the probability of further investigation into the underlying nature. Here, too, the popular reader is not likely to be disappointed; for the books present, for the most part, good mental pabulum well prepared. The scope of the brochures may be best gathered from an enumeration of the titles of those already published: (1) Hints for Health in Hot Weather, (2) Milk; (3) Colds" and Their Prevention, (4) Meat and Drink, (5) Healthful Homes, (6) The Successful Woman, (7) The Boy and the Cigarette; (8) The Care of Little Children, (9) The Plague of Mosquitoes and Flies; (10) Tonics and Stimulants; (11) Emergencies; (12) Microbes Good and Bad; (13) The Care of Babies, (14) The Efficient Worker, (15) Sexual Hygiene. The prices vary from 2 to 8 cents each copy, or from $1.50 to $5 a hundred. The last one issued, that on Sexual Hygiene, is particularly timely. It carefully avoids saying too much but what it does say is enough to suggest in what direction those who may require further information may best obtain it. The object of the league is to spread the knowledge of the laws of health among the people through the circulation of sound popular health literature.

Insurance Against Industrial Accidents.—Insurance of workmen against industrial accidents was introduced by law into Holland five years ago. At first the employers and physicians found it hard to reconcile the interests of all concerned, but as time has passed all has been amicably arranged, and the annual reports of the officials in charge of the system now comment in terms of high appreciation on the practical cooperation of the physicians. The first year or so they complained of excessive solicitude on the part of physicians, who were said to exaggerate the effects of the accidents and keep the injured workmen too long on the sick list. The profession took up the matter and discovered that two medical men had given rise to these just complaints, and the names of these two were stricken from the list of physicians eligible for the work. An Amsterdam letter in the *Wiener klinische Rundschau*, May 17, states that physicians have still to learn much in the matter of industrial accidents and their treatment. Functional results accepted as satisfactory a few years ago are no longer so regarded, especially in the matter of fractures. Impaired earning capacity from defective functioning of the limb entails extra expense and the insurance company is correspondingly dissatisfied when functional capacity is not restored. A recent meeting of the Netherlands Surgical Association was devoted to this question, the consensus of opinion being that the aim in treatment is to restore functional capacity, regardless of the original anatomic form of the limb. The best results in the majority of cases are secured by carefully individualized non-operative methods. Operative measures are necessary only in rare instances.

Sanitary Work in Louisiana.—The biennial report of the Special Medical Inspector of the Louisiana State Board of Health (1908) contains much interesting material. The work of the department is divided into the following five sections: (A) Educational, hygienic institute work; (B) Convention work; (C) Office work; (D) Legislative work; (E) Field work. The educational work will be commented on editorially in THE JOURNAL in the very near future. Of the rest, the field work is the most important, and covers an investigation of yellow fever reports; of variola and typhoid outbreaks; vital statistics; the spread of tuberculosis, particularly among negroes; the extinguishing of an outbreak of yellow fever in New Iberia in 1906, etc. Dengue, bubonic plague, diphtheria, influenza, epidemic cerebrospinal meningitis, dysentery, scarlet fever, and other diseases receive attention. The purity of the milk supply and the danger of house flies as disseminators of disease are dwelt on. Undoubtedly, however, the most noteworthy feature of the report is the Louisiana System of Hygienic Education, on which we have already commented editorially.

Meat in the Diet and Intestinal Affections.—P. Morsaline of Buenos Aires contributes an extensive article on mucomembranous enterocolitis to the *Semana Medica*, April 23. He protests against the assumption that meat is an important factor in the development of intestinal affections. Argentina is a cattle country and there is an unusual consumption of meat, and yet intestinal disorders are rare. In all his experience he has encountered only a very few cases of appendicitis or enteritis and none in the rural districts, either in his own or his colleagues' experience, and yet the cowboys live almost exclusively on meat. He admits that arthritic individuals are predisposed to such affections as they are subject to chronic autointoxication, and excess of nitrogenous food might be injurious, but individuals of this class mostly inhabit the cities. He adds that the Russian Jew immigrants are pre-eminently neuro-arthritic, and 60 per cent. of the women have colitis. Under other conditions all his observation in a meat-eating country discredits the idea that meat plays a preponderant part in the genesis of intestinal infections.

Neurasthenia from Insufficiency of the Salivary Glands.—Baccarani's experience has convinced him that the salivary glands have an important part in the elimination of toxic products generated in the body, and that their internal secretion is indispensable for the normal functioning of the economy. Absence of this internal secretion is liable to induce a syndrome in which neurasthenia predominates, as in a case he describes in the *Riforma Medica* for July 6. In extreme cases the metabolism may become gravely affected. Zagari has reported a fatal case of this kind, already mentioned in these columns.

Book Notices

AN ABRIDGEMENT OF PRACTICAL MEDICINE AND ALLIED SCIENCES. By J. Candor McLaughlin, M.D. Flexible Leather. Pp. 524. Published by the Author, Kansas City, Mo.

That it is a marvel of condensation to reduce the medical science of the present day with all its allied sciences to the compass of a vest-pocket manual goes without saying. That some important subjects should get squeezed out in the process of compression was to be expected. It is, indeed, surprising that we find so few positive misstatements. Perhaps there is a use for such books, but it is doubtful if they do not do more harm than good. The use of such a manual leads to reliance on its statements and this eventually to the conclusion that the information contained in its pages is sufficient, wihch would indicate a lower estimate of the scientific standing of practical medicine than any possessed by the laity of to-day. That the perusal of such a book can be of service in preparing for state board examinations as is confidently asserted by the author is a sad commentary on the unpractical character of such examinations.

NEUROGRAPHS. A Series of Neurologic Studies, Cases, and Notes. Edited by William Browning, Ph.B., M.D. Vol. i, No. 2. Paper. Pp. 164. Brooklyn: A. T. Huntington, 1908.

That the opportunity of the county practitioner to contribute to the progress of medical science should not be neglected is shown by the history of the development of our knowledge of Huntington's chorea. Several previous observers had noticed these cases, but the attention of the scientific world was not attracted until Dr. Huntington, a recent graduate, and then a country practitioner, reported the results of his father's and his own observations. His description was so accurate and comprehensive that it has given his name to the disease. Neurographs devotes its second number to sketches of Huntington, and also Waters, Gorman, and Lyon who published observations before him and to a consideration of the present state of our knowledge of the disease as shown in contributions by various authors. It has been possible by the historical method to trace the cases described by the early writers and to determine that they came from well defined local groups, while it has been shown that in some cases the existence of the disease can be traced to the earliest period of the colonization of New England. The disease, however, is known to exist in all European countries and is not limited to a single race, as it has been observed in the negro.

ON THE WITNESS STAND. By Hugo Münsterberg, Professor of Psychology, Harvard University. Cloth. Pp. 269. Price, $1.50. New York: The McClure Co., 1908.

Witnesses in courts of law are examined and investigated as to veracity and character, but little as to competency in observation. Münsterberg illustrates the error in this oversight by the results of experiments: Those who saw a pre-arranged quarrel write out accounts of it, and differ radically on essential points; students are asked to state the length of time between two sounds and variously estimate it from half a second to sixty seconds; the actual time being ten seconds, etc. The actions of the mind are being studied more and psychology is destined to occupy a more important position. Münsterberg takes up hypnotism, suggestion, untrue confessions, and the association test for crime, recently described in THE JOURNAL by Dr. Scripture. The book is not an elaborate treatise—only some fragmentary popular sketches which call attention to the importance from legal and humanitarian points of view of understanding how the mind operates under various conditions.

HYDROTHERAPY. By Simon Baruch, M.D., Professor of Hydrotherapy in Columbia University (College of Physicians and Surgeons), New York. Third Edition, Revised and Enlarged. Pp. 544, with illustrations. Cloth. Price, $4.00. New York: William Wood & Co., 1908.

The necessity for a special work on hydrotherapy still appears to be urgent in the view of the author of this treatise. This is one of the best books on the subject of hydrotherapy and this third edition brings up to date the quarter century's labor of the author in this field. In this edition the chapters on phthisis and insanity have been enlarged by the addition of clinical and other material. Clinical histories have been retained as furnishing not only evidence of the patient's progress under hydriatic measures, but as setting forth, clearly and forcibly, the indications for a change in methods to meet changed conditions.

THE DEVELOPMENT AMERICA, 1800 TO
1870. By Alvin A. ofessor of Clinical
Ophthalmology in the York. Cloth. Pp.
197, with illustration : W. T. Keener &
Co., 1908.

This review of the early period of American ophthalmology is an amplification of an address delivered by the author before the Section on Ophthalmology of the American Medical Association at Atlantic City, June 4, 1907. The factors which determined the development are described and brief biographic accounts of the principal actors in the drama are given. Some account is also given of the institutions that have served to further the development of ophthalmology as a separate department of medicine. The book is illustrated by the portraits of a large number of early American surgeons and forms a most worthy contribution to the history of medicine in this country.

STATE BOARD QUESTIONS AND ANSWERS. By R. Max Goepp, M.D., Professor of Clinical Medicine at the Philadelphia Polyclinic. Cloth. Pp. 684. Price, $4.00. Philadelphia: W. B. Saunders Co., 1908.

The author has taken the questions of state board examinations, many of which he finds have been repeatedly asked and has given brief answers. An effort has been made to maintain a continuity of subject matter, and a carefully arranged index makes it possible to readily find any subject. In brief, the book is a quiz-compend covering the subjects usually contained in a state board examination. Although at their best such compends are unsatisfactory, some will find this book useful. It will be of service in guiding the student to a knowledge of what points are apt to be included in an examination and hence it will direct him in his preparation.

General Surgery. Vol. II, of the Practical Medicine Series. Edited by John B. Murphy, A.M., M.D., LL.D., Professor of Surgery in Rush Medical College. Pp. 614, with illustrations. Cloth. Price, $2.00. Series 1908. Chicago: The Year Book Publishers.

The author's plan is to select representative articles on the various subjects since the literature is so abundant that it is impracticable to review or to abstract it all and keep within the limits of this handbook. The volume is well arranged and presents a full account of the advances of the year in the field of surgery. Much attention is given to the details of Bier's methods of inducing hyperemia, which are daily coming into greater prominence. The book is very fully illustrated, two full-page plates being in colors. The book forms Volume II of the annual series of year-books issued by the Year Book Publishers.

The Spectroscope. By T. Thorne Baker, F.C.S., F.R.P.S. Cloth. Pp. 130, with illustrations. Price, $1.75. New York: William Wood & Co., 1907.

This is chiefly a technical work dealing with the construction of the spectroscope and its use by the analytic chemist, especially in inorganic chemistry. It is designed to serve as an intermediate text-book between the ordinary works treating of physics and the more elaborate works on the spectroscope.

Elements of Human Physiology. By Ernest H. Starling, M.D. Lond., etc., Jodrell Professor of Physiology, University College, London. Eighth Edition. Cloth. Pp. 716. Price, $3.75 net. Chicago: W. T. Keener & Co., 1907.

This edition differs little from its predecessors. It presents briefly the essentials of physiology, and the general arrangement of the text is good. Nine pages are devoted to a general description of the ductless glands of which the author says: "Under this title have been grouped a number of organs the sole resemblance between which lies in the fact that we know little about them."

Practice of Medicine for Nurses. By George Howard Hoxie, A.M., M.D., Professor of Internal Medicine in the University of Kansas. With a Chapter on the Technic of Nursing, by Pearl L. Laptad, Principal of the Training School for Nurses of the University of Kansas. Cloth. Pp. 284. Price, $1.50. Philadelphia: W. B. Saunders Co., 1908.

The title of this book is misleading as the author states in the preface that he believes that the nurse should neither diagnose a case nor prescribe remedies, and that therefore little space has been given to differential diagnosis or to the dosage of drugs. On the whole, the book differs little from others on the same subject.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

DECAPSULATION TREATMENT OF ECLAMPSIA.

Loma Linda, Cal., June 18, 1908.

To the Editor:—Where can I find an article on the decapsulation treatment of eclampsia which describes a case in which the kidney parenchyma puffed out on incision of the capsule? Please refer me also to other articles on congestion and edema of the kidney in eclampsia and uremia as revealed by actual observation at operation.

George K. Abbott.

Answer.—The article referred to probably is one by Dr. W. T. Wiemer, "Decapsulation of Kidneys in Treatment of Eclampsia," published in *Monatschr. f. Geburtsh. u. Gynäk.*, March, 1908, and abstracted in The Journal, April 25, 1908, p. 1387. This appears to be the only article which describes a congestion of kidneys in eclampsia such that the kidney tissue bulged out on incision. Sippel noticed in 1902 that the kidneys were in a condition of increased tension in the body of a woman who had succumbed to eclampsia with persisting anuria two days after delivery. Franck, however, states that in none of the ten cases in which the operation has been performed were there any reports of an increased tension or bulging of the kidney after splitting the capsule.

The following recent articles on this subject may be consulted:

Sippel, A.: Decapsulation of Kidney in Treatment of Severe Eclampsia, *Berl. klin. Wchnschr.*, xliii, No. 49, abstracted in The Journal A. M. A., Jan. 26, 1907, p. 373.

De Bovis, R.: Unilateral Decapsulation of Kidney in Treatment of Eclampsia, *Semaine méd.*, xxvii, No. 7; abstracted in The Journal A. M. A., April 13, 1907, p. 1304.

Franck, O.: Decapsulation of Kidney in Eclampsia, *München. med. Wchnschr.*, Dec. 10, 1907.

Sippel, A.: Decapsulation or Splitting of Kidney in Eclampsia, *Zentralbl. f. Gynäk.*, Dec. 21, 1907.

ESTIMATION OF PROTEIDS IN MILK.

Pittsburg, Pa., June 24, 1908.

To the Editor:—Please give a method of estimating proteids in milk sufficiently accurate for clinical purposes. Most methods given are so complicated that a well-equipped laboratory is necessary to carry them out.

F. S. Kellogg.

Answer.—All methods for quantitative estimation of proteids in milk require a certain amount of laboratory equipment and experience—and none is easy. If accurate scales and measuring instruments are at hand the following simple, though somewhat tedious, method gives results usually sufficiently accurate for clinical purposes, although it must be admitted that it is liable to some sources of error.

Evaporate to dryness on the water bath 5 c.c. of milk, after weighing in a weighed platinum dish. This operation will take about three hours. The total solids are obtained by weighing this residue. The fat is now removed by repeatedly extracting with gasoline or ether, allowing the solvent to stand for some time over the residue without stirring and then pouring off. The residue of proteids and milk sugar is now weighed and the sugar dissolved out by boiling 50 per cent. alcohol. This leaves a residue consisting of the proteids and a part of the salts. This residue is weighed and then incinerated and the weight of the ash subtracted from the combined weight. The difference gives the weight of the proteids.

The following simple method is recommended by Austin (Manual of Clinical Chemistry): Place 5 c.c. of milk in a graduate and dilute with water to 25 c.c.; mix well and fill a graduated sedimentation tube to 5 c.c. with this dilute milk and to 15 c.c. with Esbach's solution; the whole is then to be centrifuged for 3 minutes. The amount of precipitate reckoned as cubic centimeters, multiplied by 5 for dilution, and divided by 2 for fat, equals the percentage of the whole protein content. For instance, if there is 1.2 c.c., we have $1.2 \times 5 \div 2 = 3$ per cent. No claim is made to great accuracy for this process, for the percentage varies with the amount of fat: if the fat is normal, however, the results are said to correspond very closely with the calculated amount from the nitrogen found according to the Kjeldahl process. Esbach's reagent consists of 10 gm. of picric acid and 20 gm. of citric acid in a liter of water.

BACTERIOLOGY OF MEASLES.

Pittsburg, Pa., June 19, 1908.

To the Editor:—What work has been done in the bacteriology of measles?

H. P. Kohlberger.

Answer.—After much search, the bacteriology of measles, so far as the essential cause is concerned, is still uncertain. Several recent investigators have described hemophilic bacilli in the catarrhal secretions from the involved mucous membranes, and Giarrè and Carlini have found similar bacilli in the blood. In connection with their article (*Archiv. für Kinderheilkunde*, 1907, xlvi, 262), references will be found to earlier work. The bacillus described does not stain by Gram's method, and stains unevenly with carbolfuchsin. It corresponds closely to the bacilli described in connection with influenza and whooping-cough. That this is not the real cause of measles has been rendered probable by the investigations of Hektoen (Experimental Measles: *Jour. Infect. Diseases*, vol. ii, 1905, p. 238). Pneumococci and streptococci are found as etiologic factors in most of the complications of measles.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending June 27, 1908:

LaGarde, L. A., lieut.-col., M. C., assigned to duty as attending surgeon, Denver, in addition to duties as chief surgeon Department of Colorado.

Lewis, W. F., major, M. C., left Fort Sill, Okla., with troops for Leon Springs, Texas.

Grubbs, R. B., capt., M. C., left Fort McIntosh, Texas, for Leon Springs, Texas.

Harris, H. S. T., major, M. C., leave of absence further extended one month.

Reynolds, C. R., capt., M. C., ordered to duty as commanding officer of Co. C., H. C., Army General Hospital, Washington Barracks, D. C.

Grissinger, J. W., capt., M. C., leave of absence extended to July 24.

Morris, S. J., capt., M. C., granted leave of absence for two months, about August 15.

Wickline, W. A., capt., M. C., left Army General Hospital, San Francisco, Cal., with one-half of Company B., H. C., for duty at Leon Springs, Texas.

Heysinger, J. D., capt., M. C., ordered from Key West Barracks, Fla., to Chickamauga Park, Ga., for duty.

Campbell, G. F., Guittard, A. M., Koyle, F. T., and Langenderfer, F. V., contract surgeon, relieved from duty in Philippines Division and ordered to San Francisco, Cal., by first available transport.

Hull, A. R., contract surgeon, granted leave of absence for one month.

Whinnery, J. C., dental surgeon, left Fort Columbia, Wash., for duty at Vancouver Barracks, Wash.

Waddell, R. W., dental surgeon, relieved from duty in the Philippines Division, and ordered to Fort Slocum, N. Y., for duty.

Hammond, W. G., dental surgeon, left Fort Apache, Ariz., and arrived at Whipple Barracks, Ariz., for duty.

Voorhies, H. G., dental surgeon, ordered to Fort Crook, Nebr., for temporary duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending June 27, 1908:

Blackwell, E. M., P. A. surgeon, ordered to the Naval Academy.

Stalnaker, P. R., asst.-surgeon, ordered home and granted leave for two months.

McClurg, W. A., medical director, to be placed on the retired list, Sept. 1, 1908, on his own application, on completion of thirty years' service, in accordance with a provision of the naval appropriation act of May 13, 1908.

Taylor, J. L., asst.-surgeon, ordered to the Naval Hospital, New Fort Lyon, Colo.

Bogan, F. M., P. A. surgeon, detached from the Naval Recruiting Station, Minneapolis, Minn., and ordered to the *Wisconsin*.

Lando, M. E., asst.-surgeon, ordered to the Naval Recruiting Station, Minneapolis.

Trible, G. B., asst.-surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Relief*.

Clark, G. F., asst.-surgeon, ordered to the *Lancaster*.

Allen, D. G., asst.-surgeon, ordered to the Naval Medical School, Washington, D. C.

Smith, C. W., asst.-surgeon, ordered to the Naval Hospital, Portsmouth, N. H., and to additional duty at the Naval Prison at that yard.

Kerr, W. M., asst.-surgeon, ordered to the Naval Hospital, New York, N. Y.

Wheler, W. M., surgeon, detached from the Naval Station, Cavite, P. I., and ordered home.

Brown, H. L., P. A. surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *Cleveland*.

Randall, J. A., P. A. surgeon, detached from the *Denver* and ordered to the *Rainbow*

Rodman, S. S., P. A. surgeon, detached from the *Rainbow* and ordered home.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended June 24, 1908:

Williams, L. L., surgeon, granted leave of absence for 1 month, from July 15, 1908.

Gardner, C. H., P. A. surgeon, relieved from duty at San Francisco, and directed to proceed to Wilmington, N. C., assuming command of the service at that port.

Lavinder, C. H., P. A. surgeon, relieved from duty at Wilmington, N. C., and directed to proceed to Stapleton, N. Y., reporting to the medical officer in command, for duty and assignment to quarters.

White, M. J., P. A. surgeon, granted extension of leave of absence for 15 days, from July 1, 1908.

Berry, T. D., P. A. surgeon, placed on "waiting orders," from June 1, 1908.

Manning, H. M., asst.-surgeon, directed to report to the chairman of a board of examiners at the Bureau, Washington, D. C., July 6, 1908, for the purpose of determining his fitness for promotion to the grade of P. A. surgeon.

Manning, H. M., asst.-surgeon, granted leave of absence for 7 days.

Clark, E. S., acting asst.-surgeon, granted leave of absence for 10 days, from June 11, 1908.

Rush, J. O., acting asst.-surgeon, granted leave of absence for 14 days, from July 1, 1908.

Stoddard, C. S., acting asst.-surgeon, granted leave of absence for 30 days, from June 27, 1908.

BOARD CONVENED.

A board of medical officers was convened to meet at Seattle, Wash., for the purpose of examining alien immigrants. Detail for the board: P. A. Surgeon M. W. Glover, chairman; Asst.-Surgeon C. W. Chapin; Acting Asst.-Surgeon F. R. Underwood, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the two weeks ended June 26, 1908:

SMALLPOX—UNITED STATES.

Alabama: Huntsville and vicinity, June 18, 2 cases; Mobile, May 23-June 6, 2 cases.

California: Los Angeles, May 23-June 6, 2 cases; San Francisco, May 23-June 6, 15 cases.

Illinois: Chicago, May 30-June 6, 1 case; Springfield, May 23-June 11, 6 cases.

Indiana: Fort Wayne, May 23-June 6, 11 cases; Jeffersonville, May 1-31, 30 cases; Indianapolis, May 18-June 7, 17 cases; Lafayette, June 8-15, 3 cases; South Bend, June 6-13, 4 cases; Terre Haute, May 30-June 13, 2 cases.

Iowa: Atlantic, vicinity, May 16, 12 cases; Emerson, June 1, 3 cases; Mason City, May 2-June 1, 19 cases; Ottumwa, May 30-June 6, 1 case.

Kansas: Kansas City, May 30-June 6, 5 cases; Topeka, May 31-June 6, 1 case.

Kentucky: Catlettsburg, May 24, 1 case; Covington, May 30-June 13, 1 case, 1 death.

Louisiana: New Orleans, Jan. 6-13, 3 cases.

Michigan: Detroit, June 6-13, 1 case; Grand Rapids, May 30-June 6, 1 case; Kalamazoo, 2 cases; Port Huron, May 23-30, 4 cases, 1 death; Saginaw, May 30-June 13, 5 cases.

Minnesota: Winona, May 30-June 6, 4 cases.

Missouri: Kansas City, May 23-June 13, 11 cases: St. Joseph, May 23-June 6, 13 cases; St. Louis, May 30-June 6, 1 case.

Nebraska: Friend, June 18, 1 case.

New York: Binghamton, June 1-8, 1 case; Niagara Falls, May 30-June 6, 1 case.

Ohio: Cincinnati, May 22-June 18, 9 cases; Dayton, May 30-June 13, 3 cases; Norwich, June 1, 4 cases; Toledo, May 16-June 13, 10 cases.

South Carolina: May 22-29, 2 cases.

Tennessee: Knoxville, May 30-June 6, 2 cases; Mingo Mountain, June 2, 25 cases; South Pittsburg, June 3-10, 1 case.

Washington: Spokane, May 23-June 6, 18 cases; Tacoma, May 23-30, 2 cases.

Wisconsin: La Crosse, May 30-June 13, 4 cases; Milwaukee, May 23-30, 6 cases; Racine, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, April 26-May 2, 8 cases, 3 deaths.

Porto Rico: Mayaguez, May 31-June 6, 2 cases.

SMALLPOX—FOREIGN.

Arabia: Aden, April 27-May 25, 14 deaths.

Belgium: Ghent, May 9-16, 1 death.

Brazil: Pernambuco, April 1-30, 65 deaths; Rio de Janeiro, May 3-10, 141 cases, 50 deaths.

Canada: Halifax, May 16-June 13, 17 cases; Hamilton, May 1-31, 13 cases; Winnipeg, May 31-June 6, 1 case.

Cape Colony: East London, April 16-25, 1 case, 1 death.

*China: Foochow, April 25-May 9, present; Hongkong, April 25-*May 9, 30 cases, 22 deaths; Nanking, April 25-May 1, present.

Ecuador: Guayaquil, May 9-30, 8 deaths.

Egypt: Cairo, May 13-27, 17 cases, 4 deaths.

France: Paris, May 16-23, 4 cases.

Germany, general, May 9-16, 32 cases.

Great Britain: London, May 23-30, 1 case; Southampton, May 22-30, 2 cases.

India: Bombay, May 5-19, 41 cases, 54 deaths; Calcutta, April 25-May 9, 16 cases, 15 deaths.

Italy, general, May 17-31, 57 cases; Naples, May 23-30, 2 cases; Palermo, May 9-23, 4 cases.

Japan: Osaka, May 2-23, 52 cases 29 deaths.

Java: Batavia, April 11-May 2, 10 cases.

Manchuria: Dalny, May 9-16, 1 case.

Mexico: Aguascalientes, May 31-June 7, 1 death; Mexico City, April 16-May 9, 35 deaths.

Peru: Lima, May 2-27, 2 cases.

Portugal: Lisbon, May 9-30, 10 cases.

Russia: Batoum, March 1-31, 17 cases; Moscow, May 9-23, 55 cases, 23 deaths; Odessa, May 16-23, 3 cases; Riga, May 9-30, 14 cases; St. Petersburg, May 9-16, 52 cases, 10 deaths; Warsaw, April 18-25, 5 deaths.

Siberia: Vladivostok, April 23-May 5, 1 case.

Spain: Barcelona, May 1-31, 1 death; Valencia, May 16-30, 32 cases, 6 deaths.

Turkey: Constantinople, May 17-31, 11 deaths.

Turkey in Asia: Bagdad, April 18-May 16, 83 cases, 10 deaths; Smyrna, April 14-May 5, 7 deaths.

YELLOW FEVER.

Brazil: Manaos, May 9-23, 4 cases, 4 deaths; Para, May 16-30, 5 cases, 5 deaths.

Cuba: Santiago, June 11, 1 case

Ecuador: Guayaquil, May 9-16, 2 deaths.

CHOLERA.

Ceylon: Colombo, May 2-21, 1 case, 1 death.

Cochin China: April 27-May 4, 54 cases, 45 deaths; Saignon, April 1-25, 47 cases, 28 deaths; May 2-9, 30 cases, 25 deaths.

India: Bombay, May 5-19, 3 deaths; Calcutta, April 25-May 9, 394 deaths; Rangoon, April 25-May 9, 11 deaths.

PLAGUE.

Chile: Antofagasta, May 17, 24 cases, 2 deaths; Arica, May 21, present; Valparaiso, March 21-May 14, 5 cases, 3 deaths.

China: Amoy, April 25, epidemic; Hongkong, April 25-May 9, 88 cases, 77 deaths.

Ecuador: Guayaquil, May 9-30, 27 deaths.

Egypt, General, May 13-28, 102 cases, 61 deaths; Alexandria, May 18, 1 case 2 deaths.

India: Bombay, May 5-19, 330 deaths; Calcutta, April 25-May 9, 157 deaths; Rangoon, April 25-May 9, 61 deaths.

Japan: Nara, to May 14, 7 cases; Osaka, May 17-27, 2 cases, 2 deaths.

Peru, general, May 2-23, 60 cases, 30 deaths; Callao, May 16-23, 3 cases.

Straits Settlements: Singapore, April 25, May 9, 2 deaths.

Turkey in Asia: Jiddah, Feb. 14-May 28, 71 cases, 68 deaths; Yembo, 137 cases, 126 deaths.

Venezuela: Caracas, June 4-7, 6 cases, 2 deaths; La Guaira, May 30-June 9, 10 cases, 6 deaths.

Marriages

Ralph Mills, M.D., Decatur, Ill., to Miss Ethel Bumgardner of McNabb., Ill., June 1.

Olander E. Wald, M.D., Chicago, to Miss May Augustine of West Point, Ind., June 17.

Albert Michael Wickstrom, M.D., to Emma Rühi-Maki, M.D., both of Chicago, June 10.

Arthur M. Cheetham, M.D., to Miss Agnes May Robinson, both of Cleveland, Ohio, June 18.

Hugh T. Morrison, M.D., to Miss Mary Logan Coleman, both of Springfield, Ill., June 23.

F. W. McCullough, M.D., Pittsburg, to Miss Mary A. Bortz of Greensburg, Pa., June 6.

William T. Maynard, M.D., to Miss Josephine Frances Mertz, both of Milwaukee, June 9.

Robert M. Dawson, M.D., Wittman, Md., to Miss Agnes B. Battee at Royal Oak, Md., June 10.

Walter W. Gill, M.D., Westfield, N. J., to Miss Mary C. Dunham of Alloway, N. J., June 16.

C. B. Lesher, M.D., Northumberland, Pa., to S. Mable Grier, M.D., of Salem, N. J., June 18.

Joel Isham Collier, M.D., Galveston, Texas, to Miss Susie Saunders of Navasota, Texas, June 9.

Walter W. Rhyan, M.D., Goldfield, Nev., to Miss Verda A. Elliott of South Omaha, Neb., recently.

Richard Dutton, M.D., Wakefield, Mass., to Miss Ethel Florence King of Brockton, Mass., June 9.

Murray D. Cowie, M.D., Ann Arbor, Mich., to Anna Marion Cook, M.D., of Evansville, Ind., June 13.

Otto H. G. Rosenkranz, M.D., Marietta, Ohio, to Miss Inez Adelaide Haymes of Philadelphia, June 17.

R. Granville Campbell, M.D., Lexington, Va., to Miss Ellin North Moale of Baltimore, June 20.

C. M. Kingston, M.D., Grand Forks, B. C., to Miss Martha W. Vankleek, at Armstrong, B. C., June 3.

Henry Honeyman Hazen, M.D., Washington, D. C., to Miss Laura May Ross of Malden, Mass., June 1.

Julian R. Beckwith, M.D., to Miss Louise Cameron, both of Petersburg, Va., at Anniston, Ala., June 11.

Calvin F. McDowell, M.D., New Castle, Pa., to Miss Elizabeth Up De Graph of Beaver Falls, Pa., June 18.

Joseph Lawn Thompson, M.D., Washington, D. C., to Miss Anna Letitia Waters, at Rockville, Md., June 10.

J. E. McManis, M.D., Havensville, Kan., to Miss Jane Vare Dunlap of Leavenworth, at Emporia, Kan., June 17.

Thomas Garrett Pretlow, M.D., Richmond, Va., to Miss Frances Lewellyn Ribble of Wytheville, Va., June 24.

Robert Franklin Cooper, M.D., Centreville, Ala., to Miss Emily Lamar Gibson, at Rockbridge Baths, Va., June 16.

Deaths

George Francis Heath, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1881; a member of the American Medical Association; resident physician at the University Hospital, Ann Arbor, from 1881 to 1884; alderman of Warrensburg, Mo., for two terms; four times mayor of Monroe, Mich.; for many years publisher of the *Numismatist;* one of the organizers, an early president and for many years treasurer of the American Numismatic Association; first president, and since 1892, secretary and treasurer of the Monroe County Medical Society; died at his home, June 16, from cerebral hemorrhage, after an illness of only a few hours, aged 57.

George Jenkin Preston, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1883; a member of the Medical and Chirurgical Faculty of Maryland; professor of physiology and nervous diseases in the College of Physicians and surgeons, Baltimore, since 1890; secretary of the lunacy commission of Maryland since 1898; author of many changes in the lunacy laws of the state; a widely known alienist; neurologist to several hospitals, and author of a standard work on hysteria; died at his home in Baltimore, June 17, from disease of the liver, after a long illness, aged 49.

James D. Roberts, M.D. Bellevue Hospital Medical College, New York City, 1875; a member of the Medical Society of the State of North Carolina; of Mount Olive, N. C.; superintendent of the Eastern State Hospital for the Insane, Goldsboro, from 1881 to 1887; and until recently literary editor of the *North Carolina Medical Journal;* died June 14, at Memorial Hospital, Richmond, Va., from disease of the stomach, after an illness of two weeks, aged 56.

Albert Hartsuff, M.D. Castleton (Vt.) Medical College, 1861; Brigadier General, U. S. Army, retired; who entered the army as an assistant surgeon in 1861; was made captain and brevet lieutenant colonel in 1866; ten years later was promoted to major; in 1892 to lieutenant colonel; served as chief surgeon of Camp George H. Thomas, Chickamauga, Ga., during the early part of the Spanish-American War; was made colonel in 1900; and retired a year later; died suddenly from heart disease, at his home in Detroit, June 22, aged 71.

Alexander H. Young, M.D. Jefferson Medical College, Philadelphia, 1855; a member of the American Medical Association and of the Tri-State Medical Society of Tennessee, Mississippi and Arkansas; for fifty-two years a practitioner of Ripley, Tenn.; local surgeon for the Illinois Central Railroad; died in the Presbyterian Hospital, Memphis, June 14, two days after a surgical operation, aged 77.

Oliver L. Daniel, M.D. Hospital College of Medicine, Medical Department, Central University of Kentucky, Louisville, 1896; a member of the American Medical Association; surgeon to St. Andrews' Hospital, Murphysboro, Ill.; local surgeon to the Big Muddy Coal and Iron Company; and one of the most prominent practitioners of southern Illinois; died at his home, June 21, aged 43.

Alexander Marion Elmore, M.D. Missouri Medical College, St. Louis, 1861; a member of the State Medical Association of Texas; surgeon in the Confederate service throughout the Civil War; professor of proctology in Baylor College of Medicine, Dallas, Texas; died at his home in that city, June 20, from paralysis, after an invalidism of two years, aged 70.

Clifford L. De Vinny, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1876; member of the San Joaquin County (Cal.) Medical Society; a practitioner of Stockton until a few months ago, and later a resident of Santa Cruz; died from nephritis, June 16, three months after an operation for decapsulation of the kidney, aged 59.

James F. Christal, M.D. Cooper Medical College, San Francisco, 1891; a member of the Medical Society of the State of California; at one time resident physician at the State Hospital for the Insane, Agnews; a resident of Santa Cruz; died in St. Luke's Hospital, San Francisco, June 11, after an operation for cancer of the intestines, aged 54.

Royal F. Clark, M.D. Dartmouth Medical School, Hanover, N. H., 1860; a member of the Medical Society of the State of California; surgeon in the army during the Civil War; for many years a practitioner of Los Angeles; died at his home in that city, June 15, from cerebral hemorrhage, after an invalidism of several years, aged 69.

John Randolph Webster, M.D. Rush Medical College, Chicago, 1858; Jefferson Medical College, Philadelphia, 1864; a member of the American and Military Tract medical associations, who recently celebrated his fiftieth anniversary as a practicing physician of Monmouth, Ill.; died at his home in that city, June 19, aged 72.

Joseph Henry Seaton, M.D. Kentucky School of Medicine, Louisville, 1857; surgeon of the Twenty-First Missouri Volunteer Infantry during the Civil War; for many years a practitioner of San Luis Obispo County, Cal.; died at his home in San Luis Obispo, June 13, after an illness of one week, aged 71.

Joseph M. Finnell, M.D. New York University Medical College, New York City, 1887; deputy coroner of Ramsey County, Minn.; formerly assistant health commissioner of New York City; was striken with cerebral hemorrhage, May 30, and died at St. Joseph's Hospital, St. Paul, Minn., June 13, aged 47.

Charles P. Jones, M.D. Jefferson Medical College, Philadelphia, 1849; for many years chief judge of the Orphan's Court and health officer of Worcester County, Md.; died at his home in Snow Hill, June 16, from cerebral hemorrhage, after an illness of five days, aged 83.

Henry F. Carriel, M.D. College of Physicians and Surgeons in the City of New York, 1857; superintendent of the Illinois Central Hospital for the Insane, Jacksonville, from 1870 to 1893, and thereafter a resident of Chicago; died in Jacksonville, June 23, aged 77.

Cornelius Honaker, M.D. Medical College of Ohio, Medical Department University of Cincinnati, 1884; for more than forty years a practitioner of Scioto County, Ohio, died at his home in Pond Run, June 18, from dropsy, after an invalidism of four years, aged 76

Charles Oscar Murphy, M.D. Medical School of Harvard University, Boston, 1894, a member of the American Medical Association, for five years a practitioner of New York City died in Corey Hospital, Boston, June 13, after a lingering illness aged 38

Thomas W. Small, M.D. Jefferson Medical College, Philadelphia, 1900, surgeon of the American line steamer *St Louis* died in his cabin June 19, from the effects of a gunshot wound of the brain said to have been self inflicted, with suicidal intent

Michael J. Neville, M.D. Faculty of Medicine Queen's University and Royal College of Physicians and Surgeons, Kingston Ont, 1893, of Brooklyn, N Y; surgeon to St Catherine's Hospital in that city; died in that institution June 22 aged 48

James W. Purdy, M.D. New York Medical College, New York City 1854 surgeon of the Thirty Seventh New York Volunteer Infantry, during the Civil War, died at his home at Brooklyn, June 20, from cerebral hemorrhage, aged 76

John F. Carleton, M D. University of Buffalo (N Y) Medical Department, 1886, a member of the Medical Society of the State of New York, died suddenly at his home in Waterloo, June 18, from heart disease aged 64

William Adolphus Jansen, M.D. Germany; of Miamisburg Ohio, for many years a teacher of physical culture, died in St Elizabeth's Hospital, Dayton, June 10 from senile debility after an illness of four weeks, aged 84

Robert Lambeth, M.D. Memphis (Tenn) Medical College 1853, for many years a practitioner of Mountain Grove, Mo died at his home in Springfield, Mo, June 7, from nephritis after an illness of eight weeks, aged 77

Henry R. Garner, M.D. Cooper Medical College, San Francisco, 1877; formerly of Douglas, Alaska, died at his old home in Chehalis, Wash, May 30, from heart disease, after an illness of two days, aged 66

Daniel Edward Millerick, M.D. Medical School of Harvard University, Boston, 1881, of Boston, Mass, a member of the Massachusetts Medical Society, died at his home in Stoneham Mass, June 18, aged 52

James Robert Lockhart, M D. Cincinnati College of Medicine and Surgery, 1870, for 25 years a member of the school board of Freedom, Pa, a veteran of the Civil War, died at his home, June 15, aged 66

Horace G. Westlake, M D New York University Medical College, New York City, 1850, for 58 years a practitioner of Hillsdale, N Y, died at his home in that place, June 7, after a lingering illness

Arthur J. Buckner (License, Missouri, 1884), for many years a practitioner of Northeastern Missouri, died at his home in Peakesville, June 17, from heart disease, after an illness of three months, aged 71

Daniel Madison Hurley, M D. Bellevue Hospital Medical College, New York City, 1892, died at his home in Norwood, Mass, May 31, from nephritis, after an illness of five months, aged 44

James H. Heller, M.D. Jefferson Medical College, Philadelphia, 1898, of Wilkes Barre, Pa, died at the home of his parents in that city, June 20, after an illness of two years

Claire Sims, M D. Northwestern University Womans Medical School, Chicago, 1898, formerly a practitioner of Chicago, died at her home in Citronelle, Ala, June 14, aged 31

Clyde R. Yoe, M D Vanderbilt University, Medical Department Nashville, Tenn, 1889, *died at his home in Jefferson* City, Tenn, June 17, from rheumatic endocarditis

Alexander A. Kunstlich, M D. Medical College of Indiana, Indianapolis, 1890, died at his home at Passaic, N J, June 21, after an illness of three months, aged 63

Thomas W. Folger, M.D. Atlanta (Ga) Medical College, 1876, died suddenly, June 9, at his home in Central, S C, from heart disease, aged 59

J. S. Canada, M D Louisville (Ky) Medical College, 1879 died at his home in Independence, Miss, June 14, after an illness of several weeks

Frederick Lacy Wheeler, M.D. University of Minnesota, College of Medicine and Surgery, Minneapolis 1904, of Argyle, Minn, died June 14

Elizabeth Uncapher, M.D. Homeopathic College University of Michigan, Ann Arbor, 1886, died at her home in Houston, Texas, June 18

DISTRICT OF COLUMBIA Board of Medical Supervisors Washington July 14 Secretary, Dr George C Ober, 210 B St S E, Washington

WEST VIRGINIA State Board of Health, Charleston, July 14-16 Secretary, Dr H A Barbee Pt Pleasant

MASSACHUSETTS Board of Registration in Medicine State House Boston, July 14-16 Secretary, Dr Edwin B Harvey Room 159, State House, Boston

VERMONT State Board of Medical Registration, Burlington July 14-16 Secretary, Dr W Scott Nay, Underhill

WISCONSIN Board of Medical Examiners Park Hotel, Madison, July 14-16 Secretary Dr J V Stevens Jefferson

NEW HAMPSHIRE State Board of Medical Examiners, State Library Concord July 15-16 Regent Mr H C Morrison, Concord

Ohio Board Requires Practical Tests

At the examination held by the Ohio State Board of Medical Registration and Examination at Columbus, June 8, 9, and 10 besides the usual written examination, practical examinations in pathology, bacteriology and chemistry were required In these practical tests each applicant was asked to identify pathologic specimens bacteria and urinary sediments and to make a urine analysis These tests were conducted at the same time as the written examination in one corner of the examination hall and in the presence of the entire class An extension of time equal to that required for the practical test was granted to those who were called from their written work There were 161 applicants at the examination and it required about fifty minutes for each appplicant to complete the practical test The results are said to have been highly satisfactory and the board will doubtless require these practical tests at all future examinations

Arkansas April Report.

Dr F T Murphy, secretary of the State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, April 14, 1908 The number of subjects examined in was 7, total number of questions asked, 70, percentage required to pass, 75 The total number of candidates examined was 69, of whom 38 passed, including 33 nongraduates, and 31 failed including 29 non graduates The following colleges were represented

PASSED.

College.	Year. Grad.	Per Cent.
College of P. and S., Chicago	(1902)	85
Tulane University of Louisiana	(1901)	80
Washington University, St. Louis	(1897)	87
Memphis Hosp. Med. Coll.	(1905) 87; (1906)	90

FAILED.

College.	Year. Grad.	Per Cent.
Louisville Nat. Med. Coll.	(1904)	66
University of West Tennessee	(1908)	73

LICENSED WITHOUT EXAMINATION.

There were also licensed at this examination seven old practitioners, including three non-graduates, who were granted license by reason of having been registered under the old law. The following colleges were represented:

College.	Year of Grad.
Cooper Medical Coll.	(1887)
Baltimore University	(1896)
University of the South	(1899)
Memphis Hosp. Med. Coll.	(1901)

Colorado April Report.

Dr. S. D. Van Meter, secretary of the Colorado State Board of Medical Examiners, reports the written and oral examination held at Denver, April 7, 1908. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 70. Thirty-eight applicants were licensed at this examination, five of whom passed the examination, and thirty-three were registered on presentation of satisfactory credentials, including state licenses. One of the applicants appearing for examination failed to make the required percentage. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Denver and Gross College of Medicine	(1907)	76, 79.3, 83.6
Northwestern University Medical School	(1907)	70.5
American Medical College, St. Louis	(1905)	76.5

REGISTERED ON CREDENTIALS.

College.	Year Grad.	State Licenses.
Rush Medical College	(1903) Missouri; (1907)	Texas
Northwestern Univ. Med. School	(1893) Illinois; (1905)	Illinois
American Medical Miss. College	(1903)	Illinois
Coll. of P. and S., Chicago	(1906) Illinois; (1907)	Idaho
University of Iowa	(1907)	Iowa
University of Louisville	(1885)	Missouri
Johns Hopkins Medical School	(1899)	Maryland
Boston University	(1885)	Mass.
Medico-Chirurgical College, Kansas City	(1903)	Kansas
St. Louis Medical College	(1889)	Missouri
University Med. Coll., Kansas City	(1896)	Missouri
Kansas City Medical College	(1894)	Nebraska
Central Medical College, St. Joseph	(1898)	Missouri
Omaha Medical College	(1888) Kansas; (1899) California; (1892)	Utah
Long Island College Hospital	(1901)	New York
Albany Medical College	(1899)	Illinois
Bellevue Hospital Medical College	(1892)	Illinois
Berkshire Medical College	(1867)	New York
University of Pennsylvania	(1903)	Penna
Jefferson Med. Coll.	(1903), (1904), (1905)	Penna
Hahnemann Med. Coll., Philadelphia	(1895)	Maine
Medico-Chirurgical College, Philadelphia	(1893), (1899), (1904)	Penna
University of Nashville	(1905)	Tennessee
University of Vermont	(1905)	Vermont

FAILED.

College.	Year Grad.	Per Cent.
College of P. and S., Chicago	(1907)	61.8

Montana April Report.

Dr. William C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, April 7-9, 1908. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 32, of whom 21 passed and 11 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
University of Colorado	(1906)	75
American Med. Miss. Coll.	(1907)	80.5
Rush Med. Coll.	(1904)	84.3
College of P. and S., Chicago	(1905)	83.4
College of P. and S., Baltimore	(1906)	81.6
University of Michigan	(1904) 78.2; (1906)	77.1
University of Minnesota	(1907)	75
University Med. Coll., Kansas City	(1901) 77.8; (1902)	76
Creighton Med. Coll.	(1903)	75
Bellevue Hosp. Med. Coll.	(1888)	79.1
University of Buffalo	(1901)	83.2
Medical Coll. of Ohio	(1904)	76.7
Miami Med. Coll.	(1906)	75.1
University of Virginia	(1907)	77.5, 80

Society Proceedings

COMING MEETING.

American Ophthalmological Society, New London, Conn., July 15-16
American Public Health Association, Winnipeg, Can., Aug. 25-28.
American Acad. of Ophthal. and Oto-Laryng., Cleveland, Aug. 27-29.
Medical Society of Wisconsin, Sheridan, Aug 28.

AMERICAN PEDIATRIC SOCIETY.

Annual Meeting, held at Delaware Water Gap, Pa., May 25-26, 1908.

The President, Charles Gilmore Kerley, M.D., New York, in the chair.

Officers Elected.

The following officers were elected: President, Dr. Charles B. Putnam, Boston; vice-presidents, Drs. Isaac A. Abt, Chicago, and T. S. Southworth, New York; secretary, Dr. Samuel S. Adams, Washington, D. C.; recorder, Dr. L. E. La Fetra, New York; treasurer, Dr. J. Park West, Bellaire, Ohio; member of council, Dr. Alfred Hand, Jr., Philadelphia.

The next place of meeting is to be Lenox, Mass.

Serotherapy of Epidemic Cerebrospinal Meningitis.

Dr. Simon Flexner, New York, said that he owed his ability to bring before the society a large number of figures relating to cases treated with the serum to the fact that several of the members had been very active, indeed strenuous in subjecting it to a clinical test. It had been about one year since the serum was first used in this country. He had statistics on something less than 400 cases, all diagnosed bacteriologically as well as clinically, in which the serum had been employed. In the last year the use of the serum had been somewhat modified, larger and more frequent doses being employed. A larger percentage of recoveries were shown than in previous series. Cases were treated much earlier now, which was a point of great value. The speaker emphasized this point and compared it with the early use of the diphtheria antitoxin. The serum belonged to the class of bacteriolytic sera rather than to the antitoxic class. It exerted a deleterious effect on the micro organisms; their viability was to a certain extent lost. It was not wholly devoid of antitoxic properties, but its chief value was in the destruction of the micro-organisms. The figures were based on 322 cases treated in this country and abroad, which he had analyzed. Of 247 in this country, 68 died and 179 recovered, a case mortality of 27 per cent That included not a few treated very late, and some treated early but in which the conditions were desperate, and some in which death occurred within twenty-four hours after the injection. Some underwent a marvelous change after one or two injections. There were 13 under one year of age; the youngest 4 weeks; of these 5 died and 8 recovered, a case mortality of 37.5 per cent. The child 4 weeks old recovered. There were 26 between one and two; the mortality of this series being precisely the same; 45 between two and five, of which the mortality was 22 per cent.; 62 between five and ten, of which the mortality was 11 per cent.; 57 between ten and twenty, of which the mortality was 28 per cent., and finally 44 over twenty, of which the case mortality was 45 per cent.; 47 terminated by so-called crisis and 124 by so-called lysis. He emphasized that there occurred in these cases a sudden and prompt termination of the disease; 72 of the 322 cases came from Great Britain, in which the mortality was 30 per cent., the previous mortality, not treated with the serum varying from 75 to 80 per cent. He felt that as a therapeutic agent directed to such a serious disease it should not be adopted too soon, but should be given the most thorough test until such time as there could be no doubt and it should be made by those who have observed the disease before the introduction of the serum and since. Certainly the disease was apparently modified in its intensity and whether the mortality was greatly reduced or not that was of considerable importance.

Diagnostic Value of the Chemical and Bacteriologic Examination of Cerebrospinal Fluid.

Dr. Alfred Hand, Jr., Philadelphia, referred to the importance of the exact diagnosis of the disease and said lumbar puncture furnished the means for such diagnosis. Interpretation of the fluid was sometimes easy and sometimes very difficult. If the fluid shows marked opalescence, which disappears as the fibrin forms, and the fibrinous net-work contains tubercle bacilli, diagnosis is positive. The diplococci may be found in the pus cells or in the fluid, but usually in the fluid. The fluid may be very slightly turbid so that it is difficult to recognize it. Examination should be made as soon after the fluid is obtained as possible and loopfuls transferred to slide and stained immediately. Test tube containing the fluid may be allowed to stand several hours that the fibrin net-work may be formed, which is transferred to slide with needle, spread out and fixed by heat. Chemical examination of the fluid for albumin may be made at this time. Normal amount of albumin about 0.5 per cent. Half of the fluid may be used for the phenol-hydrazin test for sugar. Examination may then be made for the pneumococcus or meningococcus. Differential count of leucocytes of great value when it can be made.

Hydrocephalus of Meningococcus Origin, with Remarks on the Serotherapy.

Drs. J. H. Mason Knox, Jr., and Frank J. Sladen, Baltimore, reviewed the literature of the subject and said that they believed the use of the serum would do much to prevent the development of hydrocephalus. They reported two cases treated with the serum; one a boy of 15, with very severe infection, ill ten days when first seen; meningococci in the fluid; improved markedly in three days; developed otitis media and paracentesis of both tympanic membranes done; hearing impaired but better when he left hospital. Second case, child of 7, seen early in the disease; received but two doses; after the first symptoms markedly improved and after the second uninterrupted convalescence. Dr. Sladen had gone carefully over the cases of meningitis before the use of the serum and found of 33 cases, 21 died and 12 recovered; lowest mortality in any one year, 43 per cent. In the last four and one-half months 21 cases admitted; all treated by lumbar puncture and injections of serum; of these 3 died and 18 recovered; mortality of 14 per cent.; the three fatal cases were of unusually virulent type.

Serotherapy of Cerebrospinal Meningitis.

Drs. Charles Hunter Dunn, Boston, and Frank Spooner Churchill, Chicago, each read a paper on this subject, reporting cases. The articles appear in full in this issue of The Journal, on pages 15 and 21, respectively.

Other Methods Compared to Serotherapy of Cerebrospinal Meningitis.

Dr. Henry Koplik, New York, said it was often apparent in considering the therapy of any disease that we sometimes lose sight, in the presence of some favorable results, of the nature of the affection, and in no disease was this more common than in cerebrospinal meningitis. As had been pointed out by Osler this disease closely resembles pneumonia in its behavior. It occurs sporadically and epidemically. In the sporadic cases we rarely meet with the severe forms. It had to be admitted that on the whole the symptomatology of the sporadic and epidemic forms was alike, but the sporadic form runs a much milder course than the epidemic form. The sporadic form rarely reveals purulent fluid at the onset. Dr. Koplik had the records of sporadic cases treated since 1899 up to the epidemic years of 1904-5. The symptomatic treatment was begun in 1899. This consisted in careful study of the symptoms and lumbar puncture repeated as often as symptoms warranted it. During 1899 and 1900 there were 8 cases of meningococcic type; during 1901 to 1903, 13 cases, thus making 21 sporadic cases. Of these, 8 patients died, a mortality of 38 per cent. Of these 8, 6 were below one year of age. There were 2 recoveries in those below one year, and 2 between the ages of one and two.

In the epidemics of 1904-5 the history of the disease was a more virulent one; some died a few hours after admission. In the first epidemic year there were 39 cases and 21 deaths, a total mortality of 53 per cent. Of these 21 deaths 13 were below thirteen years of age; 26 above the age of two. Of these 9 died, a mortality of 34 per cent. In 1905 there were 35 cases, of which 17 died, a total mortality of 48 per cent. Of the 17 deaths, 10 were below two years of age. The mortality was practically 100 per cent. in those under one year of age. Thus in the two epidemic years there were 51 cases above two years of age with a mortality of 31 per cent. There were 23 cases in these two years below two years of age, of which 78 per cent. died outright.

In the sporadic cases simple lumbar puncture saved four children below two years; in the epidemic form none were saved. Dr. Koplik did not believe in puncture unless there was distinct indication for it. To be punctured the patient must have symptoms of pressure. The serum was introduced not by a syringe but by a funnel and an attempt made to introduce the same amount of fluid that was drawn off. In the thirteen cases treated with the serum the ages varied from 3½ to 5½ years; three were below 1 year. Of those below 1 year one was discharged at 10 months. Those over 2 years recovered. In the children below 1 year that died the youngest, 3½ months, had been ill two weeks on admission.

DISCUSSION ON SEROTHERAPY OF MENINGITIS.

Dr. L. Emmett Holt, New York, said statistics were collected of 2,350 cases in the epidemic of 1904 in New York, of which the mortality, all non-serum treated, was 75 per cent., and of 350 cases in which the duration of the disease was known, 50 per cent. lasted five weeks or longer. This was very striking in comparison with the cases reported at this meeting. During epidemic years they treated 83 cases and lost every case under one year of age. He considered the showing very encouraging.

Dr. Thomas Morgan Rotch, Boston, was loath to speak of epidemic and sporadic cases; the organism ruled the disease; it did not differ in any essential way. Ward trial showed that the injections did no harm and he considered this a very important point as there was no time to wait; the injections should be given at once. He believed that sometimes life might be saved by injecting twice in the twenty-four hours. If the treatment were pushed many of the distressing sequelæ might be avoided.

Dr. Frank J. Sladen, Baltimore, said that in 21 cases in Dr. Barker's clinic the effect had been just about as described by Dr. Churchill and Dr. Dunn—a rapid drop in temperature within twenty-four hours. There was increase in polymorphonuclear leucocytes after one injection. Extracellular organisms found in the first specimens were intracellular in subsequent ones. The bacteria were destroyed—lost their staining characteristics and viability, suggesting a bacteriolytic property. The rapidity with which the symptoms disappeared also suggested an antitoxic property.

Dr. A. Jacobi, New York, thought that where subnormal temperature was noted it was due to a complication not yet understood and might be treated with something in addition to the serum, as alcohol was used in the treatment of diphtheria sometimes where the antitoxin did not benefit. He considered the results shown very encouraging.

Dr. John Lovett Morse, Boston, said that when the organisms were found in the cells and outside the cells and a culture was obtained and then the next day after giving the serum no organisms were found outside the cells and a diminished number within the cells, and no cultures, there could be no doubt. He thought lumbar puncture should be done on suspicion of the disease; one should not wait for signs of increased pressure. He thought the serum should be used early and often, at least once a day and sometimes oftener.

Dr. W. W. Wilkinson, Washington, D. C., said that of ten cases treated at the Garfield Hospital there were seven recoveries and three deaths, and of the three patients that died one had chronic hydrocephalus on admission, one was not given large enough doses at first, and the other was in a comatose condition when treatment was begun.

Dr. Samuel S. Adams, Washington D. C., emphasized the fact that by this treatment the distressing *sequelæ* of the disease were lessened. He had had one case in a child of seven months in which the pressure was so great that it burst through the fontanelle; improved *markedly after* the first injection. In a boy of thirteen with most intense symptoms, opisthotonos and convulsions, there was complete recovery. He thought the treatment offered better results than any other method of the past three decades.

(*To be continued.*)

NEBRASKA STATE MEDICAL ASSOCIATION.

Fortieth Annual Meeting, held in Lincoln, May 19-21, 1908.

Governor's Address of Welcome.

Governor Sheldon spoke of the gratitude of the state as a whole and of himself personally for the work done and the advancement made in medical legislation since the organization of the State Medical Association. He urged physicians to take a more active part during the next legislature. They better than any other class of citizens know the true cause of so many degenerates. Coming in contact as they do with the home life they know the causes of degeneracy and realize that it is high time in this country that steps should be taken to regulate the marriage laws. Governor Sheldon said it was well enough to pay attention to the divorce laws, but that it would be much better to regulate the marriage laws and thus strike at the root of the trouble. He expressed himself as heartily in favor of a law that would allow no one to marry without a certificate from a physician of good standing, stating that they are capable of bearing healthy offspring and urged the men of the medical profession to be present at the next session of the legislature with some ideas, if not a bill prepared, along these lines.

Dr. F. A. Long, Madison, responded to the address of welcome.

At 7:30 p. m. Tuesday the President's reception was held and the President delivered his address.

Officers Elected.

The following officers were elected: President, Dr. L M Shaw, Osceola; vice-presidents, Drs. F. J. Rosenburg, Lexington, and F. E. Coulter, Omaha; secretary, Dr. A. D. Wilkinson, Lincoln; treasurer, Dr. V. S. von Mansfelde, Ashland corresponding secretary and librarian, Dr. H. W. Orr, Lincoln delegates to the American Medical Association, Dr. H. Gifford, Omaha; alternate Dr. R. A. Mitchell, Lincoln.

The officers for the various sections were chosen as follows Section on Surgery—Chairman, Dr. J. P. Lord, Omaha; secretary, Dr. R. R. Hollister, Omaha. Section on Medicine—Chairman, Dr. A. Dunn, Omaha; secretary, Dr. H. J. Lehnhoff, Lincoln. Section on Gynecology and Obstetrics—Chairman, Dr. Palmer Findley, Omaha; secretary, Dr. Georgiana Grothan, Kearney.

The next meeting will be held in Omaha.

Dr. E. J. C. Sward, Oakland, secretary of the State Board of Health, made an exhaustive report of the recent work done by the State Board of Health and made important recommendations as to legislation affecting the collection of vital statistics and the regulation of matters of state sanitation.

Use of Plaster of Paris in the Treatment of Deformities.

Dr. H. Winnett Orr, Lincoln, directed attention to the fact that the popular belief in curative influence in mechanical appliances in the treatment of deformities is usually erroneous. The usual method of applying to a brace maker for treatment of all kinds of deformities leads to unfortunate delay of proper surgical and other orthopedic measures. The necessity of adequate preliminary treatment before the application of apparatus or plaster of Paris was pointed out. The points which characterize the modern treatment of deformities are the use of the open method in dividing resistant structures before attempting correction and the use of muscle and nerve transplantation to restore destroyed functions and to do away with the overaction of contracted muscles. The great usefulness of proper application of plaster of Paris and other mechanical devices in the subsequent treatment after operation was shown. Three patients were presented to illustrate the use of plaster of Paris in postoperative treatment for torticollis, hip-joint operations and also in the treatment of lateral curvature.

Acute Glaucoma.

Dr. D. C. Bryant, Omaha, read a paper covering the etiology, diagnosis, pathology and treatment of acute glaucoma and the facts on which a prognosis may be based.

Blastomycosis of the Skin.

Dr. C. L. Mullins, Broken Bow, reported a case of cutaneous blastomycosis with a complete account of the patient's symptoms and a consideration of the differential diagnosis. In addition to the clinical report and details of treatment the microscopic findings were given. He also reviewed briefly the literature of the subject and the laboratory methods for the examination of material suspected to be of this character.

Dilatation of the Stomach.

Dr. H. L. Akin, Omaha, classified dilation of the stomach into three groups: 1, the physiologically dilated stomach; 2, dilation produced by gastroptosis; 3, true dilatation. The last he selected as his subject for discussion. He discussed the factors which enter into production of dilated stomach and pointed out the conditions in which a dilatation may be brought about where either the motility was diminished or the total of contents plus resistance were disproportionately increased. As factors in the etiology he listed the various forms of indigestion and the means to be used in making a diagnosis. Under the head of treatment lavage was urged. He recommended dietetic treatment, which while necessarily variable must be accorded most careful consideration. Supporting bandages are often of assistance to the overtaxed stomach muscles. Of medicines nux vomica and strychnin are the most important therapeutic agents at our command.

Pulmonary Tuberculosis.

Dr. W. H. Mick, Denver, reported a series of twelve patients in whom a microscopic diagnosis of pulmonary tuberculosis had been made. He argued in favor of proper exercise and massage, outdoor treatment, the use of *x*-rays, which he claimed have a beneficial effect on all tuberculosis conditions, arguing that if patient did not improve in from 60 to 90 days a change in climate should be insisted on. He says that too many patients have been kept at home so long that they fail to be benefited by a change in climate or tent life. He stated that patients who improve from tuberculosis in high altitudes must remain permanently. Patients should be taught to control the cough and he asserted that tuberculin does more harm than good and argued in favor of streptolytic serum.

Conservatism in the Treatment of Appendicitis.

Dr. O. Grothan, Kearney, asserted that at the present time the manner of performing an appendectomy was not so important a topic for discussion as whether it should be performed at all. He argued that those who have operated in every case had encouraged a great deal of untimely surgery. Dr. Grothan lamented the fact that the profession could not agree on a method of treatment advocated some years ago by Ochsner, Robinson and others and argued in favor of expectant treatment with the use of opiates, relieving flatulence by rectal irrigation and complete restriction of nourishment by the mouth. The operative treatment was severely criticized and it was urged that it be used only in exceptional and very urgent cases.

Appendicitis.

Dr. H. W. Quirk, Crete, read a paper on appendicitis in which he reviews very carefully the embryology and anatomy of the abdominal cavity, especially as relating to the changes which take place in the cecum and appendix. He also reviewed the diagnosis and treatment of appendicitis from a historical standpoint and quoted extensively from literature in regard to the changes which have taken place in ideas regarding these points. He argued for the discontinuance of the opium treatment and is in favor of controlling the pain by the application of ice. He claimed that by such means he was able greatly to relieve his patients and carry many through an acute attack.

Purin Autointoxication Due to the Non-Use of Meat.

Dr. R. J. Midgley, Omaha, directed attention to the views of modern clinicians with regard to uric acid diathesis. He particularly quoted Osler and von Noorden as to their views on these questions. He pointed out that the methods of formation of uric acid in the body would be a question of only ordinary interest except that when it is present in excessive amounts we must have means at hand for promoting its combustion and elimination. Purin on the other hand must be estimated indirectly in as much as any quantity present in the body at any given time depends on the presence or absence of their destroying the enzymes. Some patients take an excess of purin-containing food while in others there has been no abnormal intake, but on account of faulty metabolism purins have accumulated. The therapeutics of these two classes of patients must necessarily therefore be quite different. He concludes that if there is a purin autointoxication it can arise from defects of meat in diet, also that this form of purin poisoning can be cured by the use of meat. Hyperacid urine is not always due to meat eating, but meat may be used as an antacid. Meat is not to be prominent in the diet except for good cause and dietetics should have more general attention.

Acute Dilatation of the Stomach.

Dr. A. S. McKinnon, Lincoln, said that this condition seems to occur most frequently following laparotomy. After a review of the literature Dr. McKinnon reported two cases in which the patients presented the classical symptoms. The first patient, aged 17, died the fourth day following operation, while the second improved without the stomach having been made the subject of operative treatment.

First Aid in Fractures.

Dr. A. B. Anderson, Pawnee City, quoted the remark of the late Dr. Senn that bad results following fractures have been the tombstone of an otherwise brilliant career of many ill-fated practitioners. The treatment of fractures is often undertaken by absolutely inexperienced physicians. He pointed out the dangers of the improperly applied fixed dressings and emphasized the importance of a careful consideration of the patient's general condition as well as of the local injury in making a diagnosis and applying treatment. He also emphasizes the importance for careful consideration of injury to soft parts associated with the fractured bone and reported cases illustrating some of the bad results that may follow inadequate diagnosis and improperly applied dressings. In conclusion he outlined some of the methods to be used in the treatment of ordinary fracture.

Fractures: Symptoms and Diagnosis.

Dr. S. C. Beede, David City, discussed the general symptoms of fractures and pointed out the subjects of error in diagnosis. He emphasized crepitus as a positive sign of fracture. He emphasized the necessity for taking into careful consideration the history of the injury and took the position that an examination should not be made except in an emergency until this had been done. The value of x-ray was pointed out, but it was emphasized that careful interpretation of the findings based on thorough anatomic knowledge was absolutely necessary.

X-Ray in the Diagnosis and Treatment of Fractures.

Dr. John Prentiss Lord, Omaha, pointed out that the use of the x-ray has disclosed the frequency with which imperfect apposition of the fragments has been obtained by the ordinary method of treatment of fractures. X-ray illuminations have rendered necessary not only great care in diagnosis and treatment but we must now explain to our patients the fact that exact apposition and perfect union are the exception rather than the rule. The x-ray has solved many of the problems of diagnosis and treatment and has eliminated a large part of the guess work in this branch of surgery. The medicolegal phase of the subject was dismissed with a suggestion that we should be more careful in our statements to patients when they think that the x-ray picture shows a bad result even when the functional use of the extremity is unimpaired. One radiograph of a fractured bone is inadequate to establish a conclusion in regard to these injuries.

Open Treatment of Fractures.

Dr. A. C. Stokes, Omaha, took the position that while most fractures fall under the care of the general practitioner they, as a rule, require the most advanced surgical skill. He pointed out the fact that operative treatment under proper precautions would produce more ideal results in fractures but emphasized the fact that in his own experience the most careful observance of surgical technic did not always protect him from having infections after operating on recent fractures. He discussed in some detail the technic of open operation for fractures of the end of the femur and spiral fractures of the shaft. He concludes that recent literature points to conservativeness in operative treatment. Many bad results are the result of inadequate diagnosis and imperfect reduction. The x-ray must be used. Fractures treated by operation heal more slowly than by the usual treatment. The callus formed is larger after operation. Fracture operations are very liable to infection. The use of wires, screws, nails, etc., is to be avoided.

The Lower Femoral Epiphysis.

Dr. B. F. Lorance, Auburn, reported a case of severe injury in a boy of nine to the soft parts of the thigh just above the knee, associated with separation of the epiphysis from the femur. The lower end of the shaft protruded through the wound a distance of about four inches. Although there was extended sloughing the patient obtained a good result.

Fractures of Condyles of the Humerus.

Dr. D. J. Reid, Crab Orchard, asserted that fractures into the joint would not result in ankylosis if they were uncomplicated and properly handled in the matter of a change in dressings, etc. He urged that the deformity in many of these fractures should be remedied by open operation. He recommended that the arm be dressed in complete flexion with a change in dressings on the seventh or eighth day in a new position. He emphasized the importance of dressing the arm in flexion so that in case of ankylosis an arm useful for all ordinary uses could be obtained.

Other Papers Read.

The following papers were also read:

"Deviation of the Septum," W. R. Hobbs, Omaha; "Bier's Hyperemia," C. W. M. Poynter, Lincoln; "Diagnosis," F. W. Conwell, Neligh; "Ruts—Fads—Improvements," F. A. Weir, Hastings; "Static Electricity," F. A. Wells, Strang; "Adding a Grain of Salt to Professional Ethics," C. J. Alger, Leigh; "Puerperal Infection with Special Reference to Prevention and Treatment," Georgiana Grothan, Kearney; "Treatment of Pneumonia," J. M. Mayhew, Lincoln; "Retroflexion of Uterus," W. O. Henry, Omaha; "Foreign Bodies in the Abdomen," Palmer Findley, Omaha; "Operative Treatment of Cancer, with Special Reference to Cancer of the Breast," J. E. Summers, Omaha; "Malnutrition and Society," F. C. Philbrick, Lincoln; "Nutritional Diseases in Infants," H. M. McClanahan, Omaha; "Drug Therapeutics," B. N. Corbin, Schuyler; "Congenital Disease of the Heart," J. Stanley Welch, Lincoln.

AMERICAN NEUROLOGICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Philadelphia, May 20-22, 1908.

(Continued from page 2106.)

The Weight of the Brain as Influenced by Nutrition or Disease.

Dr. H. H. Donaldson, Philadelphia, reported his experiments with the brains of white rats and compared these results with those observed in men. It was found that the normal brain weight begins to decrease early in life, in man in the eighteenth or twentieth year. In disease the loss of weight is greater in chronic than in acute diseases. While the loss in weight of the other tissues of man in disease amounts to 24 per cent. that of the brain is only 3 per cent. As a result of improper nutrition in otherwise healthy subjects the brain weight is reduced 4 per cent. There is no loss in the spinal cord in either case.

DISCUSSION.

Dr. J. J. Putnam, Boston, asked on what structures in the brain the loss chiefly falls, whether on the nerve elements or the myelin sheath.

Dr. B. Sachs, New York, asked if the loss in brain weight is greater or less than that of other organs or whether the brain simply partakes in the general deterioration of nutrition.

Dr. Donaldson said that the only element of loss studied was the amount of water which was found to be greater in amount in the diseased or poorly nourished brain. He said the whole reason for the inquiry was to show the truth or falsity of the general belief that the brain is unaffected by general disturbance of the body. The loss is more than in the skeleton but less than in the muscles. No comparisons had been made with other viscera.

Dr. E. C. Spitzka, New York, said that in the study of brains of distinguished men allowance had repeatedly been made for a decrease in weight up to 150 grams.

A Brain Tumor Localized and Completely Removed, With Symptomatology of Lesions Variously Distributed in the Parietal Lobes.

DRS. CHARLES K. MILLS and CHARLES H. FRAZIER, Philadelphia, reported the case of a woman 45 years of age, in whom the dominating focal symptoms were left lateral homonymous hemianopsia and hemiataxia, the latter especially in the upper extremities. There were slight hypesthesia, hypastereognosis and hemiparesis. The general symptoms were double optic neuritis, headache, occasional vertigo, nausea and vomiting. Some mental apathy and marked depression were present. A large parietal osteoplastic flap was raised and at the upper back part of the opening a large cyst was revealed. This was emptied and the entire sac removed. The patient made a good recovery from the operation. All focal symptoms disappeared but the hemianopsia which is gradually improving. The optic neuritis subsided slowly.

DISCUSSION.

DR. B. SACHS, New York, said that in four cases of his in which the tumor could not be located as there were no localizing symptoms, the optic neuritis was improved very much by exploratory operation. He believes in exploratory operation in such cases, where the tumor can not be localized.

DR. CHARLES E. BEEVOR, London, said that he had had a patient very much like this one on whom Victor Horsley operated. There was improvement but the hemianopsia persisted. The difference he thinks is due to the depth to which the tumor extends. If it extends deeply and destroys the optic radiations there will be no improvement in the hemianopsia.

DR. J. J. PUTNAM, Boston, reported the case of a patient with endothelioma of the cerebellum operated on with removal of the tumor and who continued to do well five years after the operation. In a case of hemianopsia in which the tumor was at the base of the brain involving the fifth nerve on both sides a decompression operation gave excellent results.

DR. M. ALLEN STARR said that he is in favor of decompression operation. He has had excellent results in two cases recently. There are cases which result in large hernias and death, but if one in ten can be saved the operation is justifiable. He agreed that brain operations should be done in one stage and that the surgeon should do everything to hasten the operation and diminish shock.

DR. THEODORE DILLER, Pittsburg, said that he also is in favor of the decompression operation. He had a patient recently who showed 7 diopters of optic neuritis. Ten days after operation the patient was completely relieved of headache and although his vision was only 5/200 before the operation, he could afterward read a typewritten page.

DR. MILLS said that he is in favor of the decompression operation, but that this case was presented, not as one of decompression but of radical cure.

DR. CHARLES H. FRAZIER, Philadelphia, said, in closing, that he quoted the statistics which place the operable tumors at 6 per cent. because he thought that the opinion of the medical profession, but that in his own case the operable tumors were from 15 to 20 per cent. He believes that if we would explore more routinely we would find the tumor oftener than we do and that we would find them earlier and thus get a greater percentage of operability.

Hysterical Insanity, With Report of Illustrative Cases.

DR. THEODORE DILLER and DR. GEORGE J. WRIGHT, Pittsburg, stated that hysteria may express itself chiefly by mental symptoms constituting a psychosis which may counterfeit the various other psychoses more or less closely; and this occurs more frequently than is commonly supposed. The recognition of hysterical insanity is important both from the prognostic and the therapeutic points of view. Inconsequential answers to which Ganser directed attention have done much to aid in the diagnosis and to create interest in the subject of hysterical insanity. Inconsequential and paradoxical conduct are often seen and are of great diagnostic value. On the negative side hysteria presents a psychosis which does not conform to the pattern of any of the ordinary insanities. The theatrical and dramatic features seen in hysteria generally are to be observed in the hysterical psychoses.

DISCUSSION.

DR. CHARLES L. DANA, New York, said that every writer has a different conception of hysteria, so that the subject is very puzzling. We could get along better if the term hysteria were dropped entirely. He does not think we will ever get a clear idea of psychoses so long as we try to establish an hysterical psychosis. He has never seen any clear-cut picture which he could qualify as belonging to this group although he has seen hysteria combined with some form of insanity.

DR. HENRY R. STEDMAN, Boston, said that if there is such a thing as hysterical psychosis, it must be based on physical stigmata. He has seen few cases of that type and thinks the term hysterical insanity is disappearing from our nomenclature.

DR. DILLER said that it is hard to define insanity and that he is unable to define hysteria. He thinks hysterical insanity is hysteria which presents such profound, prolonged exaggerated mental symptoms as to constitute the person in the ordinary practical way an insane person.

(To be continued.)

AMERICAN GYNECOLOGICAL SOCIETY.

Thirty-first Annual Meeting, held at Philadelphia, May 26-28, 1908.

(Continued from page 2102.)

The Heart in Shock.

DR. EUGENE BOISE, Grand Rapids, Mich., said it is generally conceded that the element of danger in shock is the very low blood pressure. It is also generally believed that the cause of this low blood pressure is vaso-motor paralysis. Dr. George W. Crile adopts this theory as the result of a large number of experiments. The author thinks that the conclusion of Dr. Crile is erroneous. Dr. Howell speaks of a cardiac shock in which the low blood pressure is due to cardioinhibitory exhaustion. Dr. Yandell Henderson thinks that shock is due to a deficiency of carbon dioxid in the blood, and that when death occurs suddenly in shock the heart is tetanically contracted. A series of experiments have apparently demonstrated that in shock the heart is in a state of tonic contraction, the degree of which varies with the degree of shock, and that treatment directed to the relief of this condition is the correct treatment for shock.

Pernicious Anemia in Pregnancy.

DR. PALMER FINDLEY, Omaha, reviewed the literature and then presented a clinical report of a case with the postmortem findings in both mother and child. As the result of his observations, he presented the following summary: (1) Pregnancy and the puerperium exercise a favorable influence on the development of pernicious anemia. (2) Women are more liable to pernicious anemia during pregnancy and the puerperium than at any other time. (3) There is no satisfactory explanation for the effect of pregnancy on the development of pernicious anemia. Frequent child-bearing, prolonged lactation, overwork, and malnutrition are predisposing factors. (4) There is a remarkable uniformity in the clinical phenomena and postmortem findings. (5) The onset of anemia is usually in the latter half of pregnancy. (6) The diagnosis is not possible at the onset, but is later determined by exclusion of other possible forms of anemia by blood examination, fatal termination, and finally by postmortem examination. (7) The child usually dies in utero or shortly after birth and has never been observed to show pernicious anemia. Spontaneous interruption of pregnancy is the rule. (8) In all well-established cases the disease has proved fatal.

DISCUSSION.

DR. RICHARD C. NORRIS, Philadelphia, has seen only one case of pernicious anemia in over 3,000 deliveries. The patient in this case entered the hospital shortly before she was delivered with only 12 per cent. hemoglobin. A characteristic of labor was a refusal of the patient's blood to clot. There was considerable oozing from the uterine cavity which persisted so as to require intrauterine packing and the use of adrenalin to control hemorrhage. The woman, however, finally died from this persistent oozing from the uterine cavity.

Suggestions in Teaching Gynecology.

DR. JOHN A. SAMPSON, Albany, N. Y., demonstrated special mechanical charts as an aid in this work, and said that three phases in the study of any of the clinical branches of medicine naturally suggested themselves. (1) The study of each disease as a science, namely, its cause, the changes in anatomy in its different stages, and, particularly important, the explanation of its symptomatology; (2) the classification of symptoms and the study of the various causes of each symptom and how these causes may be differentiated; (3) the art or technic of the clinical branch of medicine, namely, taking of the history, physical examination, diagnosis and treatment, and importance of clinical experience on the part of the student in the dispensaries, wards and hospitals or in private practice.

Hospital Gynecology.

DR. ROBERT L. DICKINSON, Brooklyn, N. Y., spoke of gynecology as a separate department, and described the character of hospital as affecting this. He spoke of the working adjustments between surgery and gynecology, and of the relations between assistants and house staff. He believes that there should be uniformity in technic where the operators are numerous, and thinks there should also be standard schedules of preparation, of outfit, of after care, etc. He spoke of the methods of exhibiting or guarding the histories of cases in wards, and also discussed the question of files, indexing, the inter relation of hospital and dispensary.

DR. I. S. STONE, Washington, D. C., read a paper on "Surgical Treatment of Prolapse of the Uterus and Bladder."

DR. HUGO EHRENFEST, St. Louis, Mo., contributed a paper with the title "Endometritis Exfoliativa."

Operations for Relief of Pelvic Diseases in Insane Women.

DR. LEROY BROUN, New York, described the operations performed during the last five years at the Manhattan State Hospital.

The pathologic conditions existing were alone considered; no account was taken of the mental state of the patients. The character of the mental disturbance was in the majority of instances unfavorable, in that the chance of a mental recovery was not good. Such patients, however, have an equal right to be given physical relief when needed. The patients receiving marked stimulus to mental recovery are those suffering from the form of insanity known as manic depression. The best results are obtained when operations are undertaken before the psychosis becomes a fixed habit. The character of the operation does not appear to have any relation to the mental benefit resulting.

Symposium on Intrapelvic vs. Abdominal Method of Dealing With Mechanical Obstruction to Delivery.

DR. RICHARD C. NORRIS, Philadelphia, referred to the factors to be studied before or during labor that promise spontaneous delivery or safe operative assistance. The actual test of labor should not be abandoned. He spoke of the methods and value of fetometry, of pelvimetry and of studies to determine the character of membranes, of cervix and of uterine energy. The status and methods of induction of premature labor for minor degrees of relative disproportion were described and personal statistics given. He spoke of the value and limitations of forceps and version. He referred to the circumstances which justify section of the pubic bone. Pubiotomy is preferable to symphyseotomy. The accidents of pubiotomy are best avoided by the most approved technic and by skilled operative delivery which includes complete preliminary dilatation of the birth canal.

DR. EDWARD REYNOLDS, Boston, said that: (1) In the absence of mechanical difficulties, intrapelvic methods are always preferable. (2) Throughout obstetrics a low maternal mortality is the most important of all considerations, and this should determine the choice whenever it is markedly variable as between the two methods. (3) Comparison should be made of maternal mortalities under differing conditions. (4) Similar comparison of the fetal mortalities and the maternal and fetal morbidities should also be made whenever the maternal mortalities are equal. (5) In difficult cases in which the necessity for some form of operative procedure can be safely predicted in advance the patient should be submitted to primary Cesarean section. (6) Limitations of the possibility of such prediction.

DR. EGBERT H. GRANDIN, New York, said that the operation of election in hospital practice and the ideal operation in both hospital and private practice is the elective Cesarean section by the abdomen. Careful consideration of these instances from every standpoint shows that such section, other things being equal, carries less risk to the woman. Symphyseotomy and pubiotomy, from the standpoint of the child, were considered. Under absolute indications the choice lies between embryotomy of the living fetus and abdominal Cesarean section. Both the Dührssen operation and the vaginal operation are of the emergency type, and concern not so much dystocia as conditions calling for rapid delivery, such as the acute toxemias, and very rarely placenta prævia. The Dührssen operation is alone allowable where the vaginal portion of the cervix has emerged into the lower uterine zone. The vaginal Cesarean section is alone allowable where the vaginal portion of the cervix is intact. It stands to reason that where the pelvis is too small for the given child or the child is too large for the given pelvis, both the Dührssen and the vaginal section are contraindicated, except as measures precedent to embryotomy.

DR. BARTON COOKE HIRST, Philadelphia, made a plea for conservatism in restoring Cesarean section. A large number of these operations are only justifiable in clinics to which the patients are transported without previous medical observation. The indication of labor two or four weeks before term obviates the necessity for the majority of Cesarean sections and should be resorted to more frequently.

DR. A. LAPTHORN SMITH, Montreal, said that the operation of Cesarean section has been so perfected that when performed by an experienced abdominal surgeon it has now hardly any higher death rate for mother and child than normal labor. This can not be said of prolonged application of forceps nor of even the best of the subpubic methods.

Development of the Technic of Gynecologic Operations.

DR. AUGUST MARTIN, Berlin, Germany, reviewed the work done by gynecologists in the past fifty years, and said the basis of the increasing value of gynecologic operations is the advance in anatomy, normal and pathologic, and in diagnosis. Asepsis insures surgical results. He said there are two routes discussed to-day, the abdominal and the vaginal; and he described the indications and limitations of each.

Abdominal and Vaginal Celiotomy; Their Indications and Technics.

DR. F. PFANNENSTIEL, Kiel, Germany, pointed out that either method is available for the majority of gynecologic operations. The route which gives primarily and secondarily the best chances of life and health for the patient is to be preferred. In all intraperitoneal procedures the best chances are given by abdominal celiotomy, as it affords the better opportunity for either radical or conservative work. In aseptic cases, tumors, extrauterine pregnancy, chronic inflammations, malformations, etc., the abdominal route is preferable. In septic cases, when the indications are that the infectious matter can be completely removed, the vaginal route is preferred, unless a complete view of the whole operative field and its surroundings is necessary. Except in early invasion of the cervix, all cases of cancer are better treated by the abdominal route; also when involvement of the appendix is suspected. Vaginal operation accomplishes most in all cases of prolapsus or descensus (genitoptosis) and movable retrouterine displacements. Here neither suspension nor the Alexander operation with or without colporrhaphy is permanent. Anterior and posterior vaginal celiotomy are used, sometimes the one, sometimes the other, and, if necessary, both. The author then pointed out the advantages of the Pfannenstiel transverse abdominal incision.

Vertical and Horizontal Amputation of the Uterus.

Dr. Howard A. Kelly, Baltimore, said that supravaginal hysterectomy in women under forty is too radical if it can be avoided. He spoke of subsection of the body of the uterus as being a better plan, retaining the uterine mucosa, cutting the flow down to normal, and preserving the function of mentsruation. He then described the methods of vertical and horizontal subsection of the uterus.

Cesarean Section Necessitated by Previous Ventrofixation.

Dr. Edwin B. Cragin, New York, said that for dystocia following ventrofixation to occur six times in the experience of one man, and to be so marked as absolutely to indicate Cesarean section, is sufficient evidence of the frequency of this sequel to the operation. As these fixation operations were all performed by different operators, the personal equation is eliminated. In spite of attention being called to the possibility of this unfortunate sequel to two ventrofixations, ventrosuspension is still quite frequently performed. An intended ventrosuspension may become a ventrofixation by accidental wound infection. A ventrosuspension which allowed an easy labor with a febrile puerperium in the first postoperative confinement, may become a ventrofixation and demand a Cesarean section for the next delivery, as occurred in the last of this series. During the child-bearing age, ventrofixation is not a safe operation for posterior displacement of the uterus.

Is Pubiotomy a Justifiable Operation?

Dr. J. Whitridge Williams, Baltimore, stated that in thirteen operations performed by the author or his assistants there were no maternal deaths, only one woman being seriously sick. All began to walk by the end of the third week and were dismissed in good condition less than one week later. In one-third of the cases there was permanent mobility between the cut ends of the bone. This did not interfere with locomotion, and possibly played a part in permitting subsequent spontaneous delivery in one patient. The operation is contra indicated when the true conjugate measures 7 cm. or less, and consequently does not enter into competition with Cesarean section. It is particularly applicable to the "border line" cases, as it affords a safe method of delivery after subjecting the patient to the test of several hours in the second stage, whereas the mortality of Cesarean section rises steadily with each hour elapsing after the onset of labor. If pubiotomy fulfils its present promise, it should entirely do away with the induction of premature labor in the treatment of contracted pelves.

Experimental Study of Hemorrhage and Its Possible Bearing on Ruptured Ectopic Pregnancy.

Dr. Hunter Robb, Cleveland, said that attempts were made to cause lesions in dogs which would correspond in severity to those present in cases of ruptured ectopic pregnancies in women. Assuming that in these experiments conditions were produced similar to those occurring in ruptured ectopic pregnancies in women, the results suggested the following conclusions, as being worthy of consideration: 1. A woman suffering from a ruptured ectopic pregnancy does not die from the hemorrhage itself. Death was caused by hemorrhage and shock which might be increased by various procedures. 2. An immediate operation might add shock to shock and so prevent recovery. 3. The hemorrhage ceases in from 15 to 20 minutes. The fact that the hemoglobin remained stationary showed that clotting had taken place. A hemorrhage that had ceased might be started up by manipulation of the tissues, and might thus be mistaken for a continuing hemorrhage. 4. The subcutaneous injection of salt improves the pulse and respiration and did not start the hemorrhage up again. 5. The use of bandages or proper weights by which the abdomen walls were approximated was likely to improve the condition of these patients.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting held April 22, 1908.

The President, Dr. Albert M. Eaton, in the Chair.

Demonstration of the Method of Taking the Opsonic Index.

Dr. Harry A. Duncan said that the theory of immunity as advocated by Wright puts most of the emphasis on the blood serum as the active protective substance of the body, especially that element of the blood which prepares the bacteria so that the leucocytes may ingest and destroy them. To measure the degree of resistance or susceptibility possessed by some patient to any disease caused by germs all that is necessary is to compare the action of the patient's blood serum on the bacteria in question with the action of the blood serum of some healthy individual. The influence of the serum on the germ is noted by observing the number of the germs which the polymorphonuclear leucocytes find suitable for ingestion. To take the opsonic index of a patient there is needed for the test, blood serum from the patient, blood serum from a healthy individual with which to compare it, an emulsion of the bacteria in question, and leucocytes washed free of all adhering serum. The blood serums are secured by centrifuging a few drops of blood which have been collected in a small pipette known as Wright's pipette. The bacterial emulsion is obtained by rubbing up in salt solution a culture of the germ in question grown on an agar slant. The corpuscles are cleaned of all their own serum by washing them repeatedly in salt solution and a 5 per cent. solution sodium citrate. The sodium citrate prevents clotting and the centrifuge separates the corpuscles from the washing fluids. Equal quantities of the patient's serum, washed corpuscles, and bacterial emulsion are drawn up into an opsonizing pipette, mixed and incubated for fifteen minutes at blood heat to give the serum an opportunity to act on the bacteria and the corpuscles a chance to ingest them. Equal quantities of the healthy serum, washed corpuscles, and bacterial emulsion are treated likewise in another opsonizing pipette. At the end of the fifteen minutes the contents of these pipettes are expelled on clean glass slides, smeared and stained. The number of bacteria ingested in 50 corpuscles acted on by the patient's serum are counted and compared with the number ingested by 50 corpuscles influenced by the healthy serum.

DISCUSSION.

Dr. Nathaniel Bowditch Potter, New York, quoted some figures illustrating the difficulty in relying on the opsonic index. In opposition to this, however, he admits that it has some value. He believes the bacterial inoculations are useful in many instances.

Dr. Nathaniel Gildersleeve regards the opsonic index of very moderate value for diagnostic purposes, but of more value in determining the size of the dose of vaccine and in interspacing the dose.

Dr. G. Morton Illman's experience with taking the opsonic index leads him to feel that it is fairly consistent. The greatest success clinically is observed in cases of tuberculosis and in staphylococcic and streptococcic conditions.

The Microscopic Diagnosis of Diseases by Blood Smears.

Dr. L. Napoleon Boston outlined the clinical evidences of unquestionable value obtained through a microscopic study of the blood after it has been smeared on cover glasses or slides.

Given a blood smear without any further knowledge of the patient from whom it has been obtained, it is possible to make a diagnosis in but a small number of diseases, i. e., malaria, filariasis, chronic plumbism, trypanosomiasis, leukemia, chlorotic anemia, and anemias. The diseases in which such blood examination may support the further clinical study of the case in question are given as anemia with reference to the particular type, pneumonia, sepsis, trichinosis, infection with intestinal parasites, and all diseases where leukocytosis is present. It is further of service in connection with acute mania, melancholia, poisoning from both mineral and gaseous substances, and conditions resulting from malnutrition, e. g., syphilis, glandular tuberculosis, etc. A full consideration is given to those diseases where living animal parasites are to be found in the circulating blood with an outline of the laboratory study.

Dr. George W. Norris demonstrated the Jacquet cardio sphygmograph, an elaboration of the old clinical sphygmograph, capable of attachment to the wrist in the usual manner.

Medicolegal

Another Court's View of Power to Require Allowance of Physical Examination

The Court of Appeals of Maryland says, on the appeal of United Railways and Electric Co. of Baltimore City vs. Cloman, a personal injury case brought by the latter party, that the defendant company moved the court to direct the plaintiff to permit the physicians of the defendant to make a physical examination of her, and also made another motion asking the court to direct her to submit to such examination by a physician to be appointed by the court. The authorities are conflicting on the subject. It is said that there is no record in the English reports of such an order, or even of such a motion. In the federal courts it is held that the court has no power to compel a plaintiff in an action for personal injuries to submit his person to a physical examination, and it was so decided in Union Pacific R. R. Co. vs. Botsford, 141 U. S. 250. The weight of authority seems to be to the contrary in the state courts of this country, although while the power is admitted many cautions and limitations are suggested, and the general rule is that it can not be demanded as a matter of right by a defendant, but the application is addressed to the sound discretion of the trial court, which will not be interfered with by an appellate court unless such discretion was manifestly abused. That seems to this court to be the correct view.

This court can not admit that the trial court has no such power in any case, for some times it may be apparent that a plaintiff is feigning, and has not suffered such injuries as he pretends he has sustained. Instances are not unknown to courts and counsel, who have had experience in such cases, in which jurors have been imposed on, and sometimes even reputable physicians who have been called on to testify on behalf of plaintiffs have been deceived. When, therefore, the ends of justice seem to require it, there can be no valid reason why an examination should not be permitted, if seasonable application is made, and the court is satisfied that no serious physical or mental injury is likely to be done the plaintiff.

Unless consent is given by the plaintiff to have the examination made by physicians of the defendant, the safe course is for the court to name some disinterested physician or physicians to make such examination, but the court and jury ought not to be required to rely on the testimony of experts employed or produced by the plaintiff, or that of the plaintiff himself, when there is any real question about the correctness of the evidence offered by a plaintiff in reference to the extent of his injuries. The practice of permitting such an examination would have a tendency to prevent frauds which are sometimes perpetrated by dishonest plaintiffs in actions for personal injuries.

As to what is a seasonable time for such an application may depend on circumstances, but it ought ordinarily to be made before the plaintiff's case is closed, and, if allowed after that, the privilege should be given him to introduce further testimony on the subject. Generally it should be done in time to avoid unnecessary delay in the trial, unless the court is satisfied by affidavits or otherwise that the defendant is taken by surprise, and the delay is necessary for the ends of justice. It might be well to adopt the practice of requiring affidavits of counsel as to the necessity for such applications, and of course the court should be satisfied that the application is made in good faith, and not merely to affect the jury, in case of refusal to submit to the examination.

Competency as Witness of Physician Disclaiming to be an Expert.—Care of Viscera.

The Supreme Court of Missouri says that it was insisted in the homicide case of State vs. Daly, that a physician who testified as an expert witness on the part of the state, and who subjected the viscera of the deceased to a chemical analysis, was incompetent to testify as such expert because he failed in his preliminary examination, and protested against being so denominated. But the court does not agree with the contention. It says that while the witness did not claim to be an expert, and protested against being denominated such, the court thinks it was more because of modesty than lack of knowledge respecting the matters to which he testified as an expert, for he showed himself to be quite familiar with the subject then under consideration, and his testimony bore the stamp of truth and honesty. Besides, the question of whether he possessed the necessary qualifications to render him competent to testify in the character of an expert was a preliminary one to be passed on by the court after the examination of the witness. The weight of the testimony of this witness, like that of any other, was for the consideration of the jury.

What Constitutes "Serious Illness"

The United States Circuit Court says, in the case of Keiper vs. Equitable Life Assurance Society of United States, that the term, "serious illness" has been construed to mean such an illness as has, or ordinarily does have, a permanent detrimental effect on the system, or renders the risk unusually hazardous. What is to be understood by "serious illness"? If any sickness which may terminate in death, then it must embrace almost every distemper in the entire catalogue of diseases. The true construction of the language must be that the applicant has never been so seriously ill as to permanently impair his constitution, and render the risk unusually hazardous.

8 Notes on X-Light. The Resistance of an X-Light Tube is not an Accurate Indication of the Degree of the Vacuum. W. Rollins, Boston.
9 Modern Medicine and Surgery in the Orient. (Concluded.) J. E. Mears, Philadelphia.

2. **Infection in Tuberculosis.**—Von Ruck holds that the tubercle bacillus is liable to be inhaled with air contaminated by infectious dust or minute sputum droplets, also that primary infection by the digestive tract undoubtedly occurs, though its frequency can not be even approximately estimated, and is more frequent in children than in adults, while the origin of tuberculosis in the abdominal cavity is less frequent than it is in the chest. He says: "It is fortunate for practical prophylaxis or treatment that the relative frequency of the different modes of infection is not of great importance."

6. **Dr. Beauperthuy and Yellow Fever Research.**—Agramonte presents documentary evidence to show that, so far back as 1854, Dr. Louis Daniel Beauperthuy attributed the propagation of yellow fever to the "striped legged mosquito." His views were published in the *Official Gazette* of Cumana, and were investigated by Dr. de Brassac on behalf of the French colonial office, who reported adversely on them. Beauper

they supposed that the mosquitoes obtained the poison from putrefying organic matter; but he recognized that they were the distributors of it, and fixed the guilt mainly on the domestic habits of the striped-legged variety.

16 *Cause of Premature Separation of the Placenta. L. Rosenberg, Brooklyn, N. Y.
17 *Is Idiopathic Epilepsy with Associated Paralysis Due to the Action of a Germ? B. R. Le Roy, Athens, Ohio.

10. **Permeability of Pylorus.**—Einhorn describes a small bucket (resembling the beads used in testing the condition of the stomach) tied to a long string of braided silk with a mark at 75 cm. It is enclosed in a gelatine capsule and swallowed about an hour after a small meal and remains in the digestive tract about three hours, the patient fasting meanwhile. The thread is tied to the ear or otherwise fastened so that it can not go beyond the 75 cm. mark. It is then drawn slowly up, usually meeting with slight resistance on passing the pylorus. The patient swallows once when the bucket has reached the entrance of the esophagus, and it is then easily withdrawn; or the bucket may be swallowed at bedtime and withdrawn in the morning. Usually it returns filled, and its contents are withdrawn with a pipette and placed in a small porcelain dish. They are usually yellowish (from bile), neutral or faintly acid, with no free hydrochloric acid. That the bucket really gets into the duodenum may be told not only by the contents, but by *x*-ray photographs.

12. **Infantile Paralysis.**—Keppler says that during the first six weeks all these patients should be left alone in the recumbent posture. The subsequent treatment he divides into: 1, Active treatment, (*a*) by the use of pendulum machines, (*b*) by the use of massage and electricity, (*c*) by the use of hydrotherapy; 2, brace treatment; 3, operative treatment, comprising tenotomy, tendon transplantation, nerve transplantation, and arthrodesis.

14. **Cholera Infantum.**—Hirshberg says that while this term is used to cover various conditions, the most virulent and dangerous form is caused by *Bacillus dysenteriæ*, which enters the body through the stomach. The scheme of treatment is to remove bacilli and their toxin by intestinal irigation and to combat exhaustion by stimulants, and otherwise treat symptoms. Half an ounce of old brandy can be taken by a child ten months old in 24 hours. Calomel and castor oil are the cathartics of choice, but stomach lavage and colon irrigation may be needed. Drugs, except opium, resorcin, and bismuth, have been overestimated. Lime water, sodium bicarbonate, and magnesia help the vomiting. Astringents usually do harm. A dilute acid may help in the later stages. In severe prostration, mustard baths, hot packs and saline infusions may be used. Hirshberg inveighs against popular superstitions that keep up the liability, the idea that it helps a child to pass from milk diet to other food, to accustom it to "taste" every dish taken by the mother, breaking down its digestion and constitutional resistance; and the superstition that children must have something to exercise their gums on. Such a desire is merely an acquired habit. Babies begin to acquire habits within ten days after birth. The remedy lies in maternal tact and judgment.

16. **Premature Separation of Placenta.**—Rosenberg says that in the cases that have come under his notice, he has found metritis due to gonorrheal infection to be a predisposing cause, the exciting cause being some slight trauma caused by the midwife or the physician. He reports a case in support of this theory.

17. **Epilepsy.**—Le Roy has settled on one germ, a spore-bearing bacillus, normally from 1 to 3 microns in length and from one-half to two-thirds of a micron in width, as a cause of the paralysis associated with epilepsy. The micro-organism is acid-fast, motile, intensely so—in certain media—is killed when grown on agar at 194 degrees F., but when grown in media, which have a small content of the silicates of calcium and magnesium, it can not be killed with prolonged boiling of the media; specimens lived that had undergone fractional boiling of the media for over two hundred hours. Growths from this specimen, grown as follows, give peculiar results: In a faintly alkaline gelatin bouillon at 98.6 degrees F. the organism resembles, when full grown, the *Bacillus typhosus;* transplanted to agar made less alkaline, and grown at 98.6 degrees F., it resembles the *B. tetani;* transferred to a faintly acid, lime, silicate, magnesia medium, it grows to full size. The medium is then boiled and set aside for a few weeks and the germ resembles the tubercle bacillus. Washed off and placed in faintly acid gelatin medium and grown for several weeks the germ will resemble the *B. diphtheriæ.* Throughout all these changes the germ will take the stain of the micro-organism, which it simulates and can be distinguished with difficulty. Under certain conditions of growth the germ becomes ultramicroscopic in form and after weeks of culture at 98.6 degrees F. it reappears. Clinically, the author has prepared an opsonin from it which has been tested in the Ohio State Insane Asylum with good results. He promises further communications on the subject.

23 Treatment of Diseases Due to Respiratory Catarrh. W. M. Richards, New York.
24 Injurious Habits and Practices of Childhood: Their Detection and Correction. K. H. Goldstone, Jersey City, N. J.

18. **Milk-Free Diet in Typhoid.**—Seibert has tested the following plan of treatment in St. Francis' Hospital: The stomach is washed out and two doses of calomel, 2 grains each, were given within two hours. Rectal irrigations with warm water were given, except when contraindicated by bowel hemorrhage, appendicitis, or peritonitis. Cold water only was given during first day, then strained rice, oatmeal, or barley soup, with extract of meat and egg yolk spiced. Other broths, and in case of great hunger, zwieback, were next given. Before each meal from fifteen to twenty-five drops of hydrochloric acid were given in half an ounce of water. Under this treatment, general symptoms improve, temperature falls, complications disappear or fail of development, the attack is shortened and the mortality reduced. In all, 338 cases have given a mortality of 3.1 per cent.

19. **Idem.**—Strong has tested in 17 cases, the method of Seibert, mentioned in the preceding article, and endorses Seibert's conclusions.

20. **Idem.**—Kemp discusses the milk-free treatment of typhoid of Seibert, which he considers based on sound scientific principles, and which he predicts will, in time to come, be generally recognized as the proper method.

25 *Relation of Iodin to Structure of the Thyroid Gland. D. Marine and W. W. Williams, Cleveland, Ohio.
26 *Lymphangitis and perilymphangitis of the Liver in Their Relations to Inflammations of the Organ. H. Oertel, New York.
27 *Recent Advances in Our Knowledge of the Underlying Chemical Principles of Diabetic Acidosis. E. H. Goodman, Philadelphia.
28 Infection with Schistosoma Japonicum in a Filipino. E. R. Whitmore, Manila, P. I.
29 *Treatment of Gonococcus Arthritis by Injections of Dead Gonococci, and the Clinical Reaction which Follows the Injections. E. E. Irons, Chicago.

25. **Iodin and Thyroid.**—Marine and Williams summarize the results of their investigations as follows: 1.

Iodin is necessary for normal thyroid activity. 2. Iodin is the main index to the physiologic value of the thyroid secretion (thyreoglobulin) to the body. 3. The percentage of iodin varies with the amount of colloid in the several degrees of hyperplasia; the colloid varies inversely with the degree of thyroid hyperplasia; the iodin varies inversely with the degree of thyroid hyperplasia. 4. The colloid gland (goiter) is the quiescent or normal state of a gland which has previously been a glandular hyperplasia and obeys all the biologic laws of a normal gland. 5. In the classification of thyroid changes (excluding infections and neoplasms) four major groups must be recognized, viz.: (a) Normal glands, (b) colloid glands, (c) hyperplastic glands (all grades), (d) complications engrafted on any of the three preceding groups. 6. The ability of the thyroid glands to store iodin depends on the degree of glandular hyperplasia rather than on the form or mode of administration of iodin. 7. The optimum therapeutic effects of iodin on the thyroid gland are only obtained with doses vastly smaller than those usually employed. 8. The percentage of iodin which a thyroid may contain is variable, but the minimal percentage necessary for the maintenance of normal gland structure is constant. (9) Commercially desiccated thyroid has a constant iodin content and, therefore, has a variable physiologic activity and therapeutic value. 10. The problem of human goiter, both anatomically and chemically, should be investigated along lines similar to those adopted for the dog.

26. **Lymphangitis of Liver.**—Oertel confines himself to a consideration of the condition of the lymphatics in what are now termed "acute," "subacute," and "chronic" inflammations of the liver. He says that inflammatory conditions of the liver are associated with an exudative lymphangitis and perilymphangitis. If, in the subsidence of the inflammatory irritation, the lymphatics are cleared, and nothing stands in the way of resorption of inflammatory irritants and products, a change to the normal may take place. If, on the other hand, the lymphatics are not cleared, they form an essential factor in the establishment of a progressing inflammation in the form of an exudative and productive or pure cirrhosis of the liver. He suggests the following very broad classification for diffuse inflammations of the liver:

> 1. Degenerative exudative hepatitis, now called acute hepatitis, in cases which are characterized in varying degrees and in varying combinations by cellular exudation taking origin from the portal spaces, by lymphangitis, perilymphangitis and cholangitis, by diffuse parenchymatous and fatty degenerations of the liver cells, and by cytolysis and bile imbibition.
>
> 2. Degenerative productive hepatitis in cases which are now grouped as subacute hepatitis, and divide them into two forms: the first with a more rapid loss of substance, grossly appears more or less granular, the second with a much more gradual loss of substance has consquently a more uniform, even distribution of connective tissue and is, therefore, smooth. Both of these may be associated with either enlargement or diminution in size of the liver. They are characterized, microscopically, by a productive cellular inflammation proceeding from the portal spaces, which is peri-insular and diffuse: a produc[illegible] ...uctive pericholangitis It is further [illegible], and more or less accentuated by, [illegible] ...gular, parenchymatous and fatty dege[illegible], cytolysis, bile imbibition, and the formation of new, mature and embryonic liver cells (bile ducts).
>
> 3. Productive hepatitis, or sclerosis of the liver (which is to be preferred to cirrhosis of the liver), and this is characterized essentially by the formation of mature, peri-insular, or diffuse connective tissue formation; depending on the loss of liver substance and the distribution of connective tissue, it is either granular or smooth and goes along with enlargement or diminution in size of the organ. It further presents very slowly progressing, irregular, parenchymatous and fatty degenerations, and fatty infiltration, cystolysis, little or moderate bile imbibition, and the formation of mature and embryonic liver cells (bile ducts).

27. **Diabetic Acidosis.**—Goodman's review of recent advances in our knowledge of the underlying chemical principles of diabetic acidosis leads him to the conclusion that of the three acetone bodies, beta-oxybutyric acid, diacetic acid, and acetone, the first-named seems at present to be the cause of acidosis, not on account, however, of any specific toxic properties, but simply on acount of its excess robbing the body of its alkaline supply. Any other acid present in similar excess might have the same result. Fat, especially that containing fatty acids, is the principal source of the acetone bodies, though they may be derived from protein. The place of formation is probably the liver.

29. **Gonococcus Arthritis.**—Irons studies this subject and describes the results of injections of dead gonococci. He concludes that systemic infections by the gonococcus tend to spontaneous recovery—some cases are acute, recovery being rapid, some more chronic, lasting months or even years. His results so far seem to indicate that in certain cases of gonococcus arthritis recovery can be hastened by the injection of dead gonococci, which should be used, however, rather in conjunction with other general measures, e. g., rest, aspiration of distended joints, massage of prostate, etc. The reliability of the clinical gonococcus reaction as a diagnostic procedure can be determined only after many tests.

32. See Abstract No. 49.

33. **Fracture of Neck of Humerus and Dislocation of Head.**—Buchanan reports this case and arrives at the following conclusions as to the mechanism involved: "It is probable that a fall on the outstretched arm or hand may cause, (1) a dislocation; that, if the body pitches forward with the hand or arm still on the ground, the force is applied in a new direction—along the line of the shaft, (2) an indentation of the neck occurs, or (3) a partial or complete separation of the head; if the body is projected further forward the force is applied in still another direction—compressing the elbow to the side, and (4) the partial cleavage of the neck is completed by a strong leverage of the arm. The treatment is: (1) Restoration of the dislocated head to the glenoid cavity by external manipulation; (2) restoration by open incision; (3) excision of the dislocated head, which seems to be the operation of choice, having been performed in 14 cases, with 2 results excellent, 6 good, 1 moderately good, and 2 deaths. That was the course adopted with success in the present case.

34. Abstracted in The Journal, Jan. 25, 1908, p. 310. The present article contains in addition some good illustrations and a tabular analysis of reported cases.

35. **Epiphyseal Displacement.**—Whitman describes the following methods based on the principle of reducing the displacement by leverage of the extremity and opposing the fragments by adjusting the attitude of the limb to conform to the separated head, or essentially in full abduction, the alignment being aided by manipulation of the inner fragment and by tension on the capsule and the surrounding muscles. The patient having been anesthetized, the adherent fragments are separated by forcible manipulation. The head is then grasped, as well as may be, by the fingers, and under traction the arm is abducted gradually to the extreme limit, the acromion serving as a fulcrum to direct the extremity of the diaphysis downward toward the epiphysis. When the fragments are in apposition the abducted arm may be drawn somewhat forward, if necessary, to assure proper adjustment. A shoulder spica is then applied, the extended arm being raised over the head by rotation of the scapula, so that one may better utilize muscular tension and the force of gravity to

fix the fragments. Two methods of bandaging are illustrated. Union is prompt.

37. Abstracted in THE JOURNAL, Jan. 18, 1908, p. 233

38. **Intractable Vomiting.**—Meyer's article is written, first, to recall to the mind of the general practitioner the fact that cases like those described clearly belong to the borderland, and that, after he has exhausted all means at his disposal a mere abdominal incision which, as a matter of course, will reveal some kinking or adhesions, is apt permanently to cure the patient; second, *to impress on the surgeon that it is un wise to refuse operation*; third, that gastroenterostomy in these cases is clearly contraindicated, in fact may result fatally. It is indicated only in cases of pyloric stenosis and for the purpose of putting at rest recurrent gastric ulcers that may have developed in the distal part of the stomach.

39. **Enterostomy in Intestinal Obstruction.**—Elsberg draws the following conclusions:

1. Operative interference for acute intestinal obstruction should very often be divided into two stages
2. Enterostomy and drainage should be the operation of choice not only in the desperate cases, but also in many patients whose condition is still a fair one
3 Prolonged search for the obstruction and its relief, in all patients excepting those in very good condition, should be delayed until the acute symptoms have been relieved by the opening and drainage of the bowel.
4. The danger of leaving behind gangrenous intestines is a small one, it is smaller than the danger from prolonged manipulations
5 When gangrenous intestine is present it is preferable to bring it outside of the abdomen and deal with it later; the obstructive symptoms being meanwhile relieved by enterostomy
6 Enterostomy, thus done, is not an "extreme, irrational and blindly advised" operation, but one that embodies a distinct therapeutic principle—alleviation of acute symptoms as the first step in the relief of a pathologic condition
7. The operation of enterostomy may permanently relieve acute intestinal obstruction
8 Fecal fistula will remain in only a small proportion of the cases in which enterostomy has been done, if the opening and drainage is made according to the Kader principle.

41 *The Crime of Gynecology C W. Barrett, Chicago.
42 *Preservation of the Ovaries Entire or in Part in Supravaginal or Panhysterectomy. R Peterson, Ann Arbor, Mich.
43 *Rupture of the Uterus Through the Cesarean Cicatrix. G L Brodhead, New York.
44 Myxosarcoma of the Round Ligament. W. Krusen, Philadelphia
45 Fibroma of the Anterior Abdominal Wall. Id.
46 *Necessity for the Artificial Feeding of Infants. L Johnson, Washington, D. C.
47 *Menorrhagia and Metrorrhagia. T. Kubo, Tokio, Japan

41. This article was published in the *Chicago Medical Recorder*, April, and was abstracted in THE JOURNAL, June 6, 1908, p. 1942.

42. **Preservation of Ovaries in Hysterectomy.**—Peterson has tabulated the results in 173 cases of hysterectomy in which both ovaries were also removed in 146, and in the remaining 27 cases, part of one ovary, one ovary, or both ovaries were retained. He examines the analysis under the following heads in relation to postoperative troubles: 1, Frequency, 2, severity; 3, age; 4, kind of operation; 5, disease; 6, duration of symptoms; 7, amount of ovarian tissue retained His conclusions are as follows: At least 10 per cent of all women regularly menstruating at the time of operation will be free from the troublesome symptoms of the artificial menopause after hysterectomy with removal of the ovaries. The percentage of women with no symptoms after similar operations will be slightly more than doubled if some ovarian tissue be retained. The severity of the symptoms of the artificial menopause is much less when the ovaries are retained after hysterectomy. It is not necessarily true that the younger the woman the more she will suffer from the symptoms of the menopause after hysterectomy with removal of the ovaries. The greatest percentage of suffering occurs in women operated on between the ages of 40 and 44; therefore, the rule that ovaries should be removed from patients over 40 when hysterectomy is performed should not be followed. The frequency and severity of the artificial menopause is not influenced in any way by the kind of hysterectomy performed, whether the ovaries be removed or retained. The severity of the symptoms of the menopause is practically the same after hysterectomies with removal of the ovaries for fibroid disease of the uterus and inflammatory disease of the appendages. Retention of ovarian tissue after hysterectomy cuts short the period from which patients usually suffer from the symptoms of the artificial menopause. The greater the amount of ovarian tissue conserved, the more will the symptoms of the artificial menopause be mitigated.

43. **Rupture of Uterus Through Cesarean Cicatrix.**—Brodhead tabulates and abstracts the reports of twenty cases, including one of his own, in which rupture of the uterus has occurred through the Cesarean scar. He summarizes the results of his investigations as follows: Rupture of the uterus through the Cesarean cicatrix is of rare occurrence. With prompt operative methods the mortality is comparatively low. When pregnancy follows Cesarean section, the patient may be safely delivered again by a section in a large percentage of cases In repeating a section, labor should be anticipated by a week or fourteen days. If section is to be repeated and labor sets in prior to the time elected for operation, Cesarean section should be performed as soon as possible after the onset of labor pains. Sterilization may be done at the time of section, if the patient so desires. Suture of the laceration has proved successful, but in some instances hysterectomy will be the method of choice.

46. **Artificial Feeding of Infants.**—Johnson considers that the increasing prevalence of artificial feeding is because every year fewer women either can or will nurse their infants. The principal factors in inability to do so are (1) heredity—alcoholism in the grandparents or inability of the maternal grandmother to nurse the present mother in infancy; (2) the artificial life of the modern women. To these Johnson adds as at least a contributory, and one that physicians can help to control, the strenuous school life of girls to-day. He reminds us that in rearing a girl we are contending with a deeper and more mysterious problem than in raising a boy, and suggests the inadvisability of continuing a parallel curriculum for boys and girls from early school days through college.

47. **Menorrhagia and Metrorrhagia.**—Kubo's elaborate article hardly lends itself to abstracting. He discusses the present idea concerning the causes of "uterine hemorrhage," enumerates the causes—general or remote, and local or direct—as described by various authors, and analyzes 97 cases from his own material, the striking feature of which is a finding of normal endometrium in 56 on histologic examination. He then discusses the material furnished by hysterectomy, partial hysterectomy, or panhysterectomy, with the result that examination of 9 cases of extirpation or partial resection of the uterus did not disclose any definite point common to all to which the uterine hemorrhage could be attributed in each case.

48 *Treatment of Tuberculosis by the Administration of Mercury. B L Wright, U S Navy
49 *Atlo Occipital Dislocation N. J. Blackwood, U S Navy

48 ***Mercurial Treatment of Tuberculosis.***—*Wright*, observing that the pulmonary tuberculosis of syphilitics improved while they were undergoing antisyphilitic treatment, placed ten tuberculous patients on mixed treatment:

℞. Hydrargyri chloridi corrosivi . . 0|00325 gr. 1/20
Potassii iodidi .... 0|324 gr. v
Sig t. i. d. in water.

The men all improved to the point where the medicine deranged the gastrointestinal tract, when it had to be distinued. Later, Wright and Bucher used hydrargyrum succinidum in deep muscular injections. Two cases are fully reported Thirty-three cases are reserved for future publication, but of the entire number 30 patients are showing improvement by reduced pulse rate and temperature, increased appetite, lessened cough, and a gain in weight, while the other five are holding their own. Most are well advanced cases Wright concludes that they have shown: (1) The almost immediate improvement in the general condition of the patient, following the administration of mercury: the slowing of the pulse. the reduction of temperature and the gain in weight. (2) That it will cure extremely advanced tuberculous ulceration of the larynx and pharynx in a re

Iodin is necessary for normal thyroid activity. 2 Iodin is the main index to the physiologic value of the thyroid secretion (thyreoglobulin) to the body. 3 The percentage of iodin varies with the amount of colloid in the several degrees of hyperplasia; the colloid varies inversely with the degree of thyroid hyperplasia, the iodin varies inversely with the degree of thyroid hyperplasia 4 The colloid gland (goiter) is the quiescent or normal state of a gland which has previously been a glandular hyperplasia and obeys all the biologic laws of a normal gland 5 In the classification of thyroid changes (excluding infections and neoplasms) four major groups must be recognized, viz: (a) Normal glands, (b) colloid glands, (c) hyperplastic glands (all grades), (d) complications engrafted on any of the three preceding groups 6. The ability of the thyroid glands to store iodin depends on the degree of glandular hyperplasia rather than on the form or mode of administration of iodin 7. The optimum therapeutic effects of iodin on the thyroid gland are only obtained with doses vastly smaller than those usually employed. 8. The percentage of iodin which a thyroid may contain is variable, but the minimal percentage necessary for the maintenance of normal gland structure is constant (9) Commercially desiccated thyroid has a constant iodin content and, therefore, has a variable physiologic activity and therapeutic value 10 The problem of human goiter, both anatomically and chemically, should be investigated along lines similar to those adopted for the dog

26. **Lymphangitis of Liver.**—Oertel confines himself to a consideration of the condition of the lymphatics in what are now termed "acute," "subacute," and "chronic" inflammations of the liver. He says that inflammatory conditions of the liver are associated with an exudative lymphangitis and perilymphangitis. If, in the subsidence of the inflammatory irritation, the lymphatics are cleared, and nothing stands in the way of resorption of inflammatory irritants and products, a change to the normal may take place If, on the other hand, the lymphatics are not cleared, they form an essential factor in the establishment of a progressing inflammation in the form of an exudative and productive or pure cirrhosis of the liver He suggests the following very broad classification for diffuse inflammations of the liver

1 Degenerative exudative hepatitis, now called acute hepatitis in cases which are characterized in varying degrees and in varying combinations by cellular exudation taking origin from the portal spaces, by lymphangitis, perilymphangitis and cholangitis by diffuse parenchymatous and fatty degenerations of the liver cells, and by cytolysis and bile imbibition.

2 Degenerative productive hepatitis in cases which are now grouped as subacute hepatitis, and divide them into two forms the first with a more rapid loss of substance, grossly appears more or less granular, the second with a much more gradual loss of substance has consquently a more uniform, even distribution of connective tissue and is, therefore, smooth Both of these may be associated with either enlargement or diminution in size of the liver They are characterized, microscopically, by a productive cellular inflammation proceeding from the portal spaces, which is peri insular and diffuse: a productive lymphangitis and a productive pericholangitis It is further characterized in varying degree, and more or less accentuated by, more slowly progressing, irregular, parenchymatous and fatty degenerations and fatty infiltration, cytolysis, bile imbibition, and the formation of new, mature and embryonic liver cells (bile ducts).

3 Productive hepatitis, or sclerosis of the liver (which is to be preferred to cirrhosis of the liver), and this is characterized essentially by the formation of mature, peri insular, or diffuse connective tissue formation; depending on the loss of liver substance and the distribution of connective tissue, it is either granular or smooth and goes along with enlargement or diminution in size of the organ It further presents very slowly progressing, irregular, parenchymatous and fatty degenerations, and fatty infiltration, cystolysis little or moderate bile imbibition and the formation of mature and embryonic liver cells (bile ducts)

27. **Diabetic Acidosis.**—Goodman's review of recent advances in our knowledge of the underlying chemical principles of diabetic acidosis leads him to the conclusion that of the three acetone bodies, beta-oxybutyric acid, diacetic acid, and acetone, the first-named seems at present to be the cause of acidosis, not on account, however, of any specific toxic properties, but simply on acount of its excess robbing the body of its alkaline supply. Any other acid present in similar excess might have the same result Fat, especially that containing fatty acids, is the principal source of the acetone bodies, though they may be derived from protein. The place of formation is probably the liver.

29. **Gonococcus Arthritis.**—Irons studies this subject and describes the results of injections of dead gonococci. He concludes that systemic infections by the gonococcus tend to spontaneous recovery—some cases are acute, recovery being rapid, some more chronic, lasting months or even years. His results so far seem to indicate that in certain cases of gonococcus arthritis recovery can be hastened by the injection of dead gonococci, which should be used, however, rather in conjunction with other general measures, e g., rest, aspiration of distended joints, massage of prostate, etc. The reliability of the clinical gonococcus reaction as a diagnostic procedure can be determined only after many tests.

32 See Abstract No 49.

33 **Fracture of Neck of Humerus and Dislocation of Head.**—Buchanan reports this case and arrives at the following conclusions as to the mechanism involved: "It is probable that a fall on the outstretched arm or hand may cause, (1) a dislocation; that, if the body pitches forward with the hand or arm still on the ground, the force is applied in a new direction—along the line of the shaft, (2) an indentation of the neck occurs, or (3) a partial or complete separation of the head; if the body is projected further forward the force is applied in still another direction—compressing the elbow to the side, and (4) the partial cleavage of the neck is completed by a strong leverage of the arm. The treatment is: (1) Restoration of the dislocated head to the glenoid cavity by external manipulation; (2) restoration by open incision; (3) excision of the dislocated head, which seems to be the operation of choice, having been performed in 14 cases, with 2 results excellent, 6 good, 1 moderately good, and 2 deaths. That was the course adopted with success in the present case.

34. Abstracted in The Journal, Jan 25, 1908, p. 310. The present article contains in addition some good illustrations and a tabular analysis of reported cases.

35. **Epiphyseal Displacement.**—Whitman describes the following methods based on the principle of reducing the displacement by leverage of the extremity and opposing the fragments by adjusting the attitude of the limb to conform to the separated head, or essentially in full abduction, the alignment being aided by manipulation of the inner fragment and by tension on the capsule and the surrounding muscles. The patient having been anesthetized, the adherent fragments are separated by forcible manipulation. The head is then grasped, as well as may be, by the fingers, and under traction the arm is abducted gradually to the extreme limit, the acromion serving as a fulcrum to direct the extremity of the diaphysis downward toward the epiphysis. When the fragments are in apposition the abducted arm may be drawn somewhat forward, if necessary, to assure proper adjustment. A shoulder spica is then applied, the extended arm being raised over the head by rotation of the scapula, so that one may better utilize muscular tension and the force of gravity to

fix the fragments. Two methods of bandaging are illustrated. Union is prompt.

37. Abstracted in THE JOURNAL, Jan. 18, 1908, p. 233

38. **Intractable Vomiting.**—Meyer's article is written, first, to recall to the mind of the general practitioner the fact that cases like those described clearly belong to the borderland, and that, after he has exhausted all means at his disposal a mere abdominal incision which, as a matter of course, will reveal some kinking or adhesions, is apt permanently to cure the patient: second, to impress on the surgeon that it is unwise to refuse operation; third, that gastroenterostomy in these cases is clearly contraindicated, in fact may result fatally. It is indicated only in cases of pyloric stenosis and for the purpose of putting at rest recurrent gastric ulcers that may have developed in the distal part of the stomach.

39. **Enterostomy in Intestinal Obstruction.**—Elsberg draws the following conclusions:

1. Operative interference for acute intestinal obstruction should very often be divided into two stages.
2. Enterostomy and drainage should be the operation of choice not only in the desperate cases, but also in many patients whose condition is still a fair one.
3. Prolonged search for the obstruction and its relief, in all patients excepting those in very good condition, should be delayed until the acute symptoms have been relieved by the opening and drainage of the bowel.
4. The danger of leaving behind gangrenous intestines is a small one, it is smaller than the danger from prolonged manipulations
5. When gangrenous intestine is present it is preferable to bring it outside of the abdomen and deal with it later; the obstructive symptoms being meanwhile relieved by enterostomy.
6. Enterostomy, thus done, is not an "extreme, irrational and blindly advised" operation, but one that embodies a distinct therapeutic principle—alleviation of acute symptoms as the first step in the relief of a pathologic condition.
7. The operation of enterostomy may permanently relieve acute intestinal obstruction.
8. Fecal fistula will remain in only a small proportion of the cases in which enterostomy has been done, if the opening and drainage is made according to the Kader principle.

46 *Necessity for the Artificial Feeding of Infants. L. Johnson, Washington, D. C.
47 *Menorrhagia and Metrorrhagia. T. Kubo, Tokio, Japan

41. This article was published in the *Chicago Medical Recorder*, April, and was abstracted in THE JOURNAL, June 6, 1908, p. 1942.

42. **Preservation of Ovaries in Hysterectomy.**—Peterson has tabulated the results in 173 cases of hysterectomy in which both ovaries were also removed in 146, and in the remaining 27 cases, part of one ovary, one ovary, or both ovaries were retained. He examines the analysis under the following heads in relation to postoperative troubles: 1, Frequency; 2, severity; 3, age; 4, kind of operation; 5, disease; 6, duration of symptoms; 7, amount of ovarian tissue retained. His conclusions are as follows: At least 10 per cent. of all women regularly menstruating at the time of operation will be free from the troublesome symptoms of the artificial menopause after hysterectomy with removal of the ovaries. The percentage of women with no symptoms after similar operations will be slightly more than doubled if some ovarian tissue be retained. The severity of the symptoms of the artificial menopause is much less when the ovaries are retained after hysterectomy. It is not necessarily true that the younger the woman the more she will suffer from the symptoms of the menopause after hysterectomy with removal of the ovaries. The greatest percentage of suffering occurs in women operated on between the ages of 40 and 44; therefore, the rule that ovaries should be removed from patients over 40 when hysterectomy is performed should not be followed. The frequency and severity of the artificial menopause is not influenced in any way by the kind of hysterectomy performed, whether the ovaries be removed or retained. The severity of the symptoms of the menopause is practically the same after hysterectomies with removal of the ovaries for fibroid disease of the uterus and inflammatory disease of the appendages. Retention of ovarian tissue after hysterectomy cuts short the period from which patients usually suffer from the symptoms of the artificial menopause. The greater the amount of ovarian tissue conserved, the more will the symptoms of the artificial menopause be mitigated.

43. **Rupture of Uterus Through Cesarean Cicatrix.**—Brodhead tabulates and abstracts the reports of twenty cases, including one of his own, in which rupture of the uterus has occured through the Cesarean scar. He summarizes the results of his investigations as follows: Rupture of the uterus through the Cesarean cicatrix is of rare occurrence. With prompt operative methods the mortality is comparatively low. When pregnancy follows Cesarean section, the patient may be safely delivered again by a section in a large percentage of cases. In repeating a section, labor should be anticipated by a week or fourteen days. If section is to be repeated and labor sets in prior to the time elected for operation, Cesarean section should be performed as soon as possible after the onset of labor pains. Sterilization may be done at the time of section, if the patient so desires. Suture of the laceration has proved successful, but in some instances hysterectomy will be the method of choice.

46. **Artificial Feeding of Infants.**—Johnson considers that the increasing prevalence of artificial feeding is because every year fewer women either can or will nurse their infants. The principal factors in inability to do so are (1) heredity—alcoholism in the grandparents or inability of the maternal grandmother to nurse the present mother in infancy; (2) the artificial life of the modern women. To these Johnson adds as at least a contributory, and one that physicians can help to control, the strenuous school life of girls to-day. He reminds us that in rearing a girl we are contending with a deeper and more mysterious problem than in raising a boy, and suggests the inadvisability of continuing a parallel curriculum for boys and girls from early school days through college.

47. **Menorrhagia and Metrorrhagia.**—Kubo's elaborate article hardly lends itself to abstracting. He discusses the present idea concerning the causes of "uterine hemorrhage," enumerates the causes—general or remote, and local or direct—as described by various authors, and analyzes 97 cases from his own material, the striking feature of which is a finding of normal endometrium in 56 on histologic examination. He then discusses the material furnished by hysterectomy, partial hysterectomy, or panhysterectomy, with the result that examination of 9 cases of extirpation or partial resection of the uterus did not disclose any definite point common to all to which the uterine hemorrhage could be attributed in each case.

48 *Treatment of Tuberculosis by the Administration of Mercury. B. L. Wright, U. S. Navy.
49 *Atlo-Occipital Dislocation. N. J. Blackwood, U. S. Navy.

48. **Mercurial Treatment of Tuberculosis.**—Wright, observing that the pulmonary tuberculosis of syphilitics improved while they were undergoing antisyphilitic treatment, placed ten tuberculous patients on mixed treatment:

℞.	Hydrargyri chloridi corrosivi......	0|00325	gr. 1/20
	Potassii iodidi	0|324	gr. v

Sig.: t. i. d. in water.

The men all improved to the point where the medicine deranged the *gastrointestinal* tract, when it had to be distinued. Later, Wright and Bucher used hydrargyrum succinidum in deep muscular injections. Two cases are fully reported. Thirty-three cases are reserved for future publication, but of the entire number 30 patients are showing improvement by reduced pulse rate and temperature, increased appetite, lessened cough, and a gain in weight, while the other five are holding their own. Most are well advanced cases. Wright concludes that they have shown: (1) The almost immediate improvement in the general condition of the patient, following the administration of mercury; the slowing of the pulse, the reduction of temperature and the gain in weight. (2) That it will cure extremely advanced tuberculous ulceration of the larynx and pharynx in a remarkably short period of time (3) That it produced marked improvement in advanced pulmonary lesions, and that it has also a decided beneficial action on tuberculous glands The patients were most carefully questioned and examined and no history or trace of syphilitic infection could be discovered. Wright, therefore, believes them to be cases of unmixed tuberculous disease

49 **Fracture Dislocation of Atlas and Axis.**—Blackwood reports this case as unique in that the patient was kept alive for 34½ hours by artificial respiration He has examined the literature of the subject exhaustively, but could find but one case similar to this as to location and character of fracture. In that case life was sustained for 3½ hours only by artificial respiration.

57 Laboratory Aids to the Diagnosis of Tuberculosis in Infants and Children T H Coffin New York
58 *Channels of Communication in Tuberculosis S M Hamill, Philadelphia

56 **Tuberculosis in Children**—McCrae's experience in regard to generalized tuberculosis in children has been that the most frequent site of involvement is the lungs, which were affected in 95 per cent In more than half the cases the following organs were affected in the stated order of frequency lymph nodes, spleen liver, intestines, meninges and kidneys Tuberculoma in the brain in the author's series, was about one fourth as frequent as meningeal involvement

58 **Tuberculosis**—Hamill discusses the various forms of infection with tuberculosis Infection through the skin, respiratory infection and alimentary infection As a result of his study he draws the following conclusions

1 It is impossible to gain any knowledge as to the port of entry from either the location or the degree of development of the tuberculous lesions
2 Fetal infection is proved but not common
3 Infection through the mouth tonsils and pharynx is of frequent occurrence and may be produced by inhalation or ingestion
4 Primary inhalation infection through the lungs does occur
5 Infection through the intestinal tract is definitely proved
6 The bronchial glands and lungs may be infected through the intestinal tract as well as through the lower respiratory tract
7 The relative significance of the various modes of infection is difficult to determine on the basis of our present knowledge since it has been clearly shown that it matters not from what point the tubercle bacillus is introduced it can eventually reach the bronchial glands and lungs without leaving any evidence of its mode of entrance It is probable however, on account of the greater exposure of these portions of the body, that infection through the upper respiratory and alimentary tracts is the most common and next to this for similar reason, through the lower respiratory and intestinal tracts As to which of the latter two constitutes the more frequent channel it would seem that the nature of the exposure should prove a determining factor. If infection occurs when the bacillus is introduced with the food or carried to the lips or mouth in kissing, or by infected hands, nipples toys drinking cups or the various feeding utensils, it must also certainly be by the alimentary tract If on the other hand the bacilli laden dust or droplets are inspired they may be conveyed directly to the lungs and there produce pulmonary and bronchial gland infections

60 This article was published in THE JOURNAL, March 14, 1908 p 868

66 **Influenza.**—Gill combats statements made by some medical men that no treatment is necessary or is of any special value. Besides the usual measures of ventilation, avoidance of overcrowding, proper care of colds and bronchial inflammations, nursing, etc, he begins treatment with calomel followed by a saline, then by a warm bath for diaphoresis and small quantities of cold water to relieve thirst and produce diuresis For pain he gives antipyretics Temperature above 105 F. is best combated by hydrotherapy; a tub bath, if possible, the wet pack if a trained nurse is available. and cold sponging under other circumstances For sleeplessness a warm sponge bath at night and warm applications to the spine are indicated, with hypnotics if necessary. For cough and bronchial irritation small doses of codein may be given; in the marked prostration that follows, supporting measures are indicated, such as strychnin, caffein, alcohol. As to diet, food is in the beginning always repugnant, and care, therefore, should be exercised in its administration lest from lack of assimilation distressing symptoms be aroused. Cold or acidulated water, fermented milk foods, properly prepared broths, etc. Convalescence is usually prolonged and discouraging and demands an abundance of easily digested foods and tonics, such as iron, arsenic, nux vomica, and quinin with mineral acid; also carefully regulated exercise to avoid fatigue. Massage and electricity may be useful.

68 Abstracted in THE JOURNAL, Oct 26, 1907, p 1468.

70 **Tobacco Amblyopia.**—Dowling, as the result of investigations among tobacco users employed in tobacco factories considers tobacco amblyopia the most common of all toxic amblyopias He thinks the negroes enjoy immunity in this regard Those chiefly affected are males between 35 and 68. There is gradual but progressive loss of visual acuteness Luminous objects dazzle the sight These patients see better in the evening than in the bright daylight They complain of a glimmering mist Persistent contraction of both pupils is a common symptom Ophthalmoscopically, first redness of the optic papilla, later anemia, and finally atrophy, is found. He discusses the properties of nicotine and its action on the red blood corpuscles and the oxyhemoglobin The prognosis is good if the patient comes early under treatment—chief of which is absolute prohibition of tobacco in any form. From six to twelve weeks is necessary to effect a cure Strychnin, the physiologic antagonist of nicotin, is useful.

71 **Tobacco and the Heart**—Mitchell's conclusions are as follows

1 Many men can smoke moderately for a lifetime without manifest injury
2 Excessive smoking is always injurious sooner or later
3 What constitutes "excess" differs with the individual, some men bear tobacco so badly that they should avoid it altogether. Two cigars a day may be excess for one man while another observes no special effects from several
4 In some individuals, ill effects from smoking are not observed until many years of indulgence, when gradually, or sometimes suddenly, they realize that the customary smoke produces some irregularity palpitation, angina or other disturbance
5 In the immature, the use of tobacco in any form is highly injurious interfering with the normal development of the mental powers producing various nervous disturbances especially nervous disturbance of the heart as manifested in palpitation, arrhythmia and weakness
6 Cigarette smoking as seen in this country, is more injurious than either pipe or cigar and more difficult for the victim to abandon No doubt the principal reason for this is found in the

common habit of inhaling the smoke. The nasal cavities present an enormous surface of mucous membrane, so that in the practice of inhalation more nicotine is absorbed. In addition there is the fact that from the short, loosely packed cigarette practically all the nicotine is taken hot into the respiratory passages. In the tightly rolled cigar the smoke has more time to cool down and much of its alkaloid is deposited in the butt of the cigar. In the pipe the smoke is cooled and the nicotine deposited in the stem. Another reason why we more frequently see pernicious effects from cigarette smoking, is the fact that it is the common form of smoking in the early years of life.

7. The characteristic symptoms of tobacco heart are palpitation, irregularity, irritability, anginal pains, absence of organic murmurs, prompt recovery on abandonment of the habit. Pseudoangina pectoris is not infrequent.

88. **Chronic Myocarditis.**—Carmichael concludes that while many diseases, age, sex and habit, are possible, they are not essentially etiologic factors of the fibroid type. The mechanism of the changes in heart muscle is not clearly defined. Arteriosclerosis of the peripheral trunks in heart lesions may not be accepted as presumptive evidence of myocardial affection, save in cases in which endocardial complication is absolutely excluded. Even there its value is only presumptive. The mechanism of sudden death (exclusive of rupture) must be due to sudden and absolute inhibition of contractile impulse resulting in asystole. The analogy with the Stokes-Adams syndrome suggests that the same pathologic process governs both phenomena and is supported by the pathologic findings. The fibrotic changes may be considered a result of a cycle of three events: (a) Sclerosis of the coronary arteries resulting in deficient blood supply, i. e., anemia of the heart; (b) dilatation the direct result of anemia from weakening of the heart muscle; (c) fibrotic change due in part to the primary coronary arteritis and in part to the dilatation which lengthens the course and diminishes the caliber of the cardiac vessels. Fibrotic changes once established are permanent, with a tendency toward progression, uninfluenced by any known therapy, but in the earlier stages the tendency to progression may be overcome by hygiene. The symptoms are so vague that diagnosis can be merely presumptive. The use of cardiants, especially digitalis, to stimulate contraction, without lessening resistance, is irrational and tends to favor progress of the lesion. Opium, as advocated by Musser, is a most valuable remedy when disturbed compensation gives rise to nervousness and apprehension. It acts as a cardiac tonic, reduces peripheral resistance, quiets nervous tendencies, steadies respiration, allays dyspnea, and gives rest, mental and physical. Cardiac depressants, e. g., aconite and veratrum, may be used with caution in small doses if carefully watched. In some cases they give distinct benefit.

97. **Volkmann's Ischemic Paralysis.**—Jones has discontinued all operative measures and now uses the following simple procedure: He cuts out of zinc or sheet iron five splints, which will fit the patient's fingers when extended. An assistant flexes the wrist fully and holds it forcibly and steadily in that position; then the fingers are relaxed and each must be separately splinted. The wrist is then released and the patient is directed systematically to attempt to extend the now very contracted metacarpophalangeal range, which can be done after a few days sufficiently to admit of the application of a splint from the finger tops to the wrist joint, the wrist being fully flexed to admit of this. The fingers are therefore bound in five splints and over them the hand is fixed in a splint which reaches to the wrist. For several days the hand is exercised in the direction of extension and a splint is applied, over the other splints, extending from finger tips to elbow, and is at intervals altered so that by degrees the wrist is fully extended. For some weeks this position is maintained until all contractile elasticity is lost. The splints are then removed and the hand is massaged. By this method every structure is stretched in the order of its tension. The results are satisfactory.

99. **Fracture of Radius.**—Erving summarizes his article as follows: Fracture of the radial head and neck, occurring alone, although formerly considered a rare curiosity, is not uncommon, is being observed with increasing frequency, and should always be considered in injuries of the elbow joint. The chief cause of the fracture is a fall on the outstretched hand, with the elbow extended, direct lateral blows occurring much less frequently. In uncomplicated cases without displacement diagnosis is often very difficult, as severe pain on pressure over the radial head, increased on attempted supination, is the only constant sign and is not peculiar to this condition, but occurs also in severe sprains of the lateral ligament. The differential diagnosis from partial dislocation of the radius by elongation in children, fractures of the capitellum humeri and external condyle, and sprain of the lateral ligament is especially difficult. The assistance of radiograms is of great value in cases without displacement of fragments, and in complicated lesions in which the condition is masked by much swelling, often furnishes the only means of diagnosis. The treatment in fractures without displacement is mobilization, massage, and passive movements; in the more severe

markably short period of time (3) That it produced marked improvement in advanced pulmonary lesions, and that it has also a decided beneficial action on tuberculous glands The patients were most carefully questioned and examined and no history or trace of syphilitic infection could be discovered. Wright, therefore, believes them to be cases of unmixed tuberculous disease.

49 **Fracture Dislocation of Atlas and Axis.**—Blackwood reports this case as unique in that the patient was kept alive for 34½ hours by artificial respiration He has examined the literature of the subject exhaustively, but could find but one case similar to this as to location and character of fracture In that case life was sustained for 3½ hours only by artificial respiration.

58 *Channels of Communication in Tuberculosis S M Hamill, Philadelphia

56 **Tuberculosis in Children**—McCrae's experience in regard to generalized tuberculosis in children has been that the most frequent site of involvement is the lungs, which were affected in 95 per cent In more than half the cases the following organs were affected in the stated order of frequency lymph nodes, spleen liver, intestines, meninges and kidneys Tuberculoma in the brain in the author's series, was about one fourth as frequent as meningeal involvement

58 **Tuberculosis**—Hamill discusses the various forms of infection with tuberculosis Infection through the skin, respiratory infection and alimentary infection As a result of his study he draws the following conclusions·

1 It is impossible to gain any knowledge as to the port of entry from either the location or the degree of development of the tuberculous lesions
2 Fetal infection is proved but not common
3 Infection through the mouth tonsils and pharynx is of frequent occurrence and may be produced by inhalation or ingestion
4 Primary inhalation infection through the lungs does occur
5 Infection through the intestinal tract is definitely proved
6 The bronchial glands and lungs may be infected through the intestinal tract as well as through the lower respiratory tract
7 The relative significance of the various modes of infection is difficult to determine on the basis of our present knowledge since it has been clearly shown that it matters not from what point the tubercle bacillus is introduced it can eventually reach the bronchial glands and lungs without leaving any evidence of its mode of entrance It is probable however, on account of the greater exposure of these portions of the body, that *infection through the upper respiratory and alimentary tracts is the most common*, and next to this for similar reason, through the lower respiratory and intestinal tracts As to which of the latter two constitutes the more frequent channel it would seem that the nature of the exposure should prove a determining factor *If infection occurs when the bacillus is introduced with the food or carried to the lips or mouth in kissing, or by infected hands, nipples, toys, drinking cups or the various feeding utensils, it must also certainly be by the alimentary tract If on the other hand the bacilli laden dust or droplets are inspired they may be conveyed directly to the lungs* and there produce pulmonary and bronchial gland infections

66 *Therapeutics of Influenza J C Gill Chicago

60. This article was published in THE JOURNAL, March 14, 1908 p 868.

66. **Influenza.**—Gill combats statements made by some medical men that no treatment is necessary or is of any special value. Besides the usual measures of ventilation, avoidance of overcrowding, proper care of colds and bronchial inflammations, nursing, etc, he begins treatment with calomel followed by a saline, then by a warm bath for diaphoresis and small quantities of cold water to relieve thirst and produce diuresis For pain he gives antipyretics. Temperature above 105 F. is best combated by hydrotherapy; a tub bath, if possible, the wet pack if a trained nurse is available. and cold sponging under other circumstances. For sleeplessness a warm sponge bath at night and warm applications to the spine are indicated, with hypnotics if necessary For cough and bronchial irritation small doses of codein may be given; in the marked prostration that follows, supporting measures are indicated, such as strychnin. caffein, alcohol As to diet, food is in the beginning always repugnant, and care, therefore, should be exercised in its administration lest from lack of assimilation distressing symptoms be aroused. Cold or acidulated water, fermented milk foods, properly prepared broths, etc. Convalescence is usually prolonged and discouraging and demands an abundance of easily digested foods and tonics, such as iron, arsenic, nux vomica. and quinin with mineral acid; also carefully regulated exercise to avoid fatigue. Massage and electricity may be useful.

68. Abstracted in THE JOURNAL, Oct 26, 1907. p 1468.

70 **Tobacco Amblyopia.**—Dowling, as the result of investigations among tobacco users employed in tobacco factories considers tobacco amblyopia the most common of all toxic amblyopias. He thinks the negroes enjoy immunity in this regard. Those chiefly affected are males between 35 and 68. There is gradual but progressive loss of visual acuteness. Luminous objects dazzle the sight These patients see better in the evening than in the bright daylight They complain of a glimmering mist Persistent contraction of both pupils is a common symptom Ophthalmoscopically, first redness of the optic papilla, later anemia, and finally atrophy, is found. He discusses the properties of nicotine and its action on the red blood corpuscles and the oxyhemoglobin The prognosis is good if the patient comes early under treatment—chief of which is absolute prohibition of tobacco in any form. From six to twelve weeks is necessary to effect a cure. Strychnin, the physiologic antagonist of nicotin, is useful

71. **Tobacco and the Heart.**—Mitchell's conclusions are as follows·

1 Many men can smoke moderately for a lifetime without manifest injury
2 Excessive smoking is always injurious sooner or later.
3 What constitutes "excess" differs with the individual; some men bear tobacco so badly that they should avoid it altogether. Two cigars a day may be excess for one man while another observes no special effects from several
4 In some individuals, ill effects from smoking are not observed until many years of indulgence, when gradually, or sometimes suddenly, they realize that the customary smoke produces some irregularity, palpitation, angina or other disturbance
5 In the immature, the use of tobacco in any form is highly injurious interfering with the normal development of the mental powers producing various nervous disturbances especially nervous disturbance of the heart as manifested in palpitation, arrhythmia and weakness
6 Cigarette smoking *as seen in this country*, is more injurious than either pipe or cigar and more difficult for the victim to abandon No doubt the principal reason for this is found in the

common habit of inhaling the smoke The nasal cavities present an enormous surface of mucous membrane, so that in the practice of inhalation more nicotine is absorbed In addition there is the fact that from the short, loosely packed cigarette practically all the nicotine is taken hot into the respiratory passages In the tightly rolled cigar the smoke has more time to cool down and much of its alkaloid is deposited in the butt of the cigar In the pipe the smoke is cooled and the nicotine deposited in the stem Another reason why we more frequently see pernicious effects from cigarette smoking, is the fact that it is the common form of smoking in the early years of life.

7 The characteristic symptoms of tobacco heart are palpitation, irregularity, irritability, anginal pains, absence of organic murmurs prompt recovery on abandonment of the habit Pseudoangina pectoris is not infrequent.

88 **Chronic Myocarditis.**—Carmichael concludes that while many diseases, age, sex and habit, are possible, they are not essentially etiologic factors of the fibroid type. The mechanism of the changes in heart muscle is not clearly defined Arteriosclerosis of the peripheral trunks in heart lesions may not be accepted as presumptive evidence of myocardial affection, save in cases in which endocardial complication is absolutely excluded. Even there its value is only presumptive The mechanism of sudden death (exclusive of rupture) must be due to sudden and absolute inhibition of contractile impulse resulting in asystole. The analogy with the Stokes-Adams syndrome suggests that the same pathologic process governs both phenomena and is supported by the pathologic findings The fibrotic changes may be considered a result of a cycle of three events: (a) Sclerosis of the coronary arteries resulting in deficient blood supply, i e., anemia of the heart; (b) dilatation the direct result of anemia from weakening of the heart muscle; (c) fibrotic change due in part to the primary coronary arteritis and in part to the dilatation which lengthens the course and diminishes the caliber of the cardiac vessels Fibrotic changes once established are permanent, with a tendency toward progression, uninfluenced by any known therapy, but in the earlier stages the tendency to progression may be overcome by hygiene. The symptoms are so vague that diagnosis can be merely presumptive The use of cardiants, especially digitalis, to stimulate contraction, without lessening resistance, is irrational and tends to favor progress of the lesion Opium, as advocated by Musser, is a most valuable remedy when disturbed compensation gives rise to nervousness and apprehension. It acts as a cardiac tonic, reduces peripheral resistance, quiets nervous tendencies, steadies respiration, allays dyspnea, and gives rest, mental and physical. Cardiac depressants, e. g., aconite and veratrum, may be used with caution in small doses if carefully watched. In some cases they give distinct benefit.

97. **Volkmann's Ischemic Paralysis.**—Jones has discontinued all operative measures and now uses the following simple procedure: He cuts out of zinc or sheet iron five splints, which will fit the patient's fingers when extended. An assistant flexes the wrist fully and holds it forcibly and steadily *in that position; then the fingers are relaxed and each must* be separately splinted. The wrist is then released and the patient is directed systematically to attempt to extend the now very contracted metacarpophalangeal range, which can be done after a few days sufficiently to admit of the application of a splint from the finger tops to the wrist joint, the wrist being fully flexed to admit of this. The fingers are therefore bound in five splints and over them the hand is fixed in a splint which reaches to the wrist For several days the hand is exercised in the direction of extension and a splint is applied, over the other splints, extending from finger tips to elbow, and is at intervals altered so that by degrees the wrist is fully extended . For some weeks this position is maintained until all contractile elasticity is lost. The splints are then removed and the hand is massaged. By this method every structure is stretched in the order of its tension The results are satisfactory.

99 **Fracture of Radius.**—Erving summarizes his article as follows: Fracture of the radial head and neck, occurring alone, although formerly considered a rare curiosity, is not uncommon, is being observed with increasing frequency, and should always be considered in injuries of the elbow joint. The chief cause of the fracture is a fall on the outstretched hand, with the elbow extended, direct lateral blows occurring much less frequently. In uncomplicated cases without displacement diagnosis is often very difficult, as severe pain on pressure over the radial head, increased on attempted supination, is the only constant sign and is not peculiar to this condition, but occurs also in severe sprains of the lateral ligament. The differential diagnosis from partial dislocation of the radius by elongation in children, fractures of the capitellum humeri and external condyle, and sprain of the lateral ligament is especially difficult The assistance of radiograms is of great value in cases without displacement of fragments, and in complicated lesions in which the condition is masked by much swelling, often furnishes the only means of diagnosis. The treatment in fractures without displacement is mobilization, massage, and passive movements; in the more severe

types, fixation for two weeks at a right angle, followed by massage and passive movements at once; in fractures with marked or irreducible displacements and in old cases with loss of function, excision of the radial head, followed by active treatment. In long-standing cases the prognosis of excision is influenced largely by the secondary changes in the joint consequent on disuse. The fracture should always be considered of a serious nature and a grave prognosis as to future perfect function should be given in all cases with displacement, especially when treated by conservative measures alone.

110. **Trichinosis.**—White describes the invasion by the parasites and the changes produced by them in man—gastroenteritis and eosinophilia. He discusses mixed infection and describes the changes in the muscle fibers and in the interstitial tissues. In diagnosis the following are of direct moment: Gastrointestinal symptoms, beginning from a few hours to two to four days after ingestion of the infected meat, early and persistent fever, myositis, edema and cutaneous phenomena, and eosinophilia, which is very characteristic. He describes the differential diagnosis between trichinosis and typhoid, influenza, subacute disseminated polymyositis, acute rheumatism and meningitis. The results of an autopsy in a fatal case are given.

114. **The Placenta and the Child.**—Manton publishes some investigations into the relation existing between the weight of the placenta and that of the new born child, which lead him to the conclusion that, as a rule, the development of the placenta goes forward with that of the child, and that its size (weight) may be taken ordinarily as an index to the weight development of the latter. While there may be variations in individual cases, these will not be sufficiently numerous greatly to influence the *normal* weight ratio between child and placenta, viz., as 6 + : 1.

3. **Antirabic Serum.**—Semple summarizes his paper as follows: By immunizing horses with fixed rabies virus it is pos-

sible to prepare a serum having well-marked rabicidal properties. Normal horse serum is devoid of these properties The rabicidal properties of this serum can be tested by mixing it with a fixed virus and subsequently using the mixture to inoculate susceptible animals, such as rabbits, subdurally The indications for the use of such a serum would seem to be an adjunct to the ordinary method of treatment in severely bitten patients and late cases. In severely bitten patients coming early for treatment it might also be injected into the wounds and the contiguous tissues. The serum of patients after undergoing a course of antirabic treatment also gives evidence of containing rabicidal substances and the presence of these substances can be demonstrated in a manner similar to that mentioned above. Normal serum is devoid of these properties. The rabicidal substances in the serum of a patient after antirabic treatment are a possible index of the amount of immunity conferred and the efficacy of treatment Prolonged treatment confers a higher degree of immunity, as judged by the rabicidal effects of the serum on fixed virus, than treatment extended over a shorter period of time. The blood of a patient suffering from hydrophobia fails to infect rabbits when inoculated subdurally. The serum of a patient in the early stages of hydrophobia is capable of prolonging the incubation period for fixed virus when mixed *in vitro* and inoculated subdurally in rabbits.

7. **Ruptured Appendix.**—Malcolm reports a case in which what was held to be an emergency operation for appendicitis was done. At the time "there was nothing to indicate that the patient's condition was a serious one, but it was considered wise to operate at once. The preliminary pain, the acute collapse, the subsequent quiescent state of the intestine, the fulness of the abdomen, and the continued resistance over the cecum, together with the absence of inflammatory symptoms and of a defined swelling led us to this decision." The appendix was found gangrenous and it ruptured during operation Malcolm comments as follows: "I have published other cases in which a similar absence of inflammation has been observed in association with gangrene formation and if we consider those cases to which the term 'explosive' or 'fulminating appendicitis' have been given, much may be said in favor of the view that the illness depends on a gangrene formation which has caused no symptoms until perforation occurred by separation of the dead part. Such cases are often characterized at first by symptoms of shock and by collapse, which are easily accounted for as the results of perforation, but not as those of an acute inflammation. The inflammatory symptoms which do arise later may often be most satisfactorily interpreted as the effects of the presence of a gangrenous patch or of the discharge of the contents of the bowel into the peritoneal sac"

15 *Treatment of Fracture of Femur in Newborn R Jones
16 Plastic Resection of Breast and Its Bearing on Preliminary Incision of Breast Tumors C H Whiteford

9 **Cerebral Influenza.**—Saundby discusses exhaustively the literature of this subject and adds some cases of his own. Bacteriologic examination has revealed either no organism or streptococci, Pfeiffer's bacilli, or pneumococci. These cases represent not one but several conditions—a series of purely influenzal origin and in which influenza forms merely the soil in which other disease germs find the conditions favorable to their development. True cerebral influenza may cause a state of cerebral intoxication, which passes off without doing serious damage; or the poison may cause intense and fatal congestion with minute meningeal hemorrhages; or inflammation of the meninges; or finally acute hemorrhagic encephalitis associated sometimes with hemorrhage or red softening. In another category are cases of streptococcal or pneumococcal meningitis occurring after influenza and other forms of focal cerebral infection. Saundby describes the symptomatology as follows: "Usually after a short period, ranging from one to four days, during which the patient shows signs only of catarrh—and in some cases even this history may be wanting—he is seized with intense headache, with or without vomiting, or neuralgia, or an epileptic or apoplectic fit or aphasia, or there may be facial paralysis, monoplegia or hemiplegia, for the cerebral symptoms may be ushered in by any one of these symptoms There may be a preliminary period of restlessness, with or without delirium; in others stupor or unconsciousness develops gradually or suddenly. There is usually fever, varying in amount. The muscles are often rigid; stiffness of the neck, opisthotonos, and especially contraction of the masseters and trismus, have been frequently noted; there may be twitchings of the limbs or clonic spasms of the head or extremities, disturbances of vision, inequality or irregularity of the pupils, paralysis of the sphincters and *tâche cérébrale.* The reflexes are generally preserved and there has been no mention of the presence of Kernig's sign. Optic neuritis is occasionally seen: albuminuria has been generally absent, but was observed once or twice; Cheyne-Stokes breathing has been noted in a few cases." The prognosis should be guarded but not hopeless. In treatment we are comparatively powerless and must look forward hopefully to the extension of antitoxic therapy. We might try small doses of quinin as recommended by Sir William Broadbent. Feed the patient with milk or egg beaten up or with *café au lait.* Rectal enemata may be given if swallowing is difficult, or in case of relaxed sphincter, subcutaneous injection of ½ a pint to a pint of physiologic saline solution. Hypodermic injections of caffein, 5 grains (0.32), in heart collapse, or camphorated oil, 10 to 15 minims of a 1 in 10 solution.

13. **Cancer of Tongue.**—Paul has operated by Butlin's method during the years 1905-1907 in 35 cases of cancer of the tongue, with 2 deaths, both from sepsis Lately he has followed Sir James Barr's suggestion to combat this danger, viz., in patients whose condition suggests a serious risk of sepsis, a dose of polyvalent serum is given before operation. His experience of Butlin's operation is entirely favorable. In the primary operation on the tongue, however, he advocates for all but the most favorable cases, a return to Kocher's and Syme's incisions, which involve the clearance of submental and submaxillary areas at the primary operation, but leave the carotid area and what may be considered necessary of the posterior triangle, for the second operation.

14. **Cancer of the Mouth.**—Fells discusses buccal cancer on a basis of 209 operations with 6 deaths. In 58 cases the cheek was affected, in 68 the lower jaw, in 5 the upper jaw, in 18 the tongue, in 21 the lips Of preliminary measures for lessening hemorrhage the administration of calcium chlorid for two or three days before operation appeared of distinct value. A preliminary tracheotomy is valuable, especially when help is short. The large raw surfaces left in the mouth are painted with Whitehead's varnish or zinc chlorid solution. There were no subsequent lung complications and no serious septic troubles

15 **Fracture of Femur in Newborn.**—Jones has treated 26 cases of fracture of femora occurring during delivery. A newly born baby with a broken thigh requires a great deal of management, and a splint is all but useless, which is not easily and surely retained or does not allow the child to be moved, fed, or washed. He uses a Thomas' knee splint. Extension plasters are applied to the leg below the fracture and the limb is passed through the ring which encircles the thigh at the groin, and is padded over with felt, leather and impervious oilskin. The thigh is pulled, and extension is maintained by the plasters which are affixed to the lower end of the splint. A bandage is placed round the limb and no further treatment is needed than now and again to extend the limb by pulling on the plasters. The infant can be carried, nursed, left to play on the floor, without displacement of fragments. It can be applied in five minutes without an anesthetic

25 **Vaccine Therapy and Immunization.**—Wright says the possibilities of vaccine therapy in the treatment of localized bacterial infections have been only very incompletely explored. After enumerating some of the problems that remain for solution in the future, Wright addresses himself to a detailed consideration of the two following questions: 1. Would it not be possible to achieve and maintain an increased output of protective substances apart from periodic measurements of the content of the blood in protective substances? Associated with this is the question as to whether the technic which we use for the determination of the opsonic index gives accurate and useful results. 2. What is the best method of directing such protective agencies as a patient may be possessed of or may acquire by immunization, to the destruction of the microbes in the focus of infection? In answer to the first question the following two suggestions have been made: 1 By clinical observations and blood testings such a knowledge of the effects of bacterial vaccines has been arrived at, as would make it possible to guarantee a good result from the inoculation of a definite quantum of a standardized vaccine. 2 The clinical symptoms of the patient will furnish to the immunizator a guide by which he may regulate the immunization procedures. The latter, again, he considers in relation to four different classes of cases, as follows (a) Localized infections of such nature that the clinical observer can immediately either see for himself or learn of every change that occurs in the focus of infection; (b) strictly localized infections where conditions are unfavorable to observations of changes in their condition; (c) acute febrile conditions; (d) cases in which all local and general symptoms are in abeyance or have returned to the condition which prevailed previous to inoculation He discusses these propositions in detail under the foregoing heads, and concludes that "while we can in many cases conduct our immunizations aright by relying on the experience gained in the past and on clinical investigation, there are whole classes of cases—these being cases where the only hope for the patient is to be found in the proper conduct of immunization procedures—where the clinical symptoms can not be trusted to furnish the necessary guide. In regard to the accessory question, as to the accuracy and usefulness of the index estimation, he answers in the affirmative With regard to the second question he considers in detail the general question of the distribution of antibacterial agents in the normal organism; the nature of the inflammatory reaction which supervenes on a bacterial invasion of the tissues, and changes in the distribution of the antibacterial agents which are effected by that reaction; cases in which microbes have survived the inflammatory reaction that has supervened on their invasion, and have established themselves in a nidus in the tissues. He then considers the therapeutic measures by which we may bring the antibacterial agencies of the circulating blood into effective operation on the microbes in a nidus of infection. These he enumerates and discusses under the following subheads: 1. Measures favoring the transfer of antibacterial agencies from the blood to the site of infection. 2. Measures opening the way for the entrance of the antibacterial element into the focus of infection. Finally he considers the organization of the profession for the work of therapeutic immunization.

26. **Accuracy of Opsonic Index.**—Fleming publishes his observations in Wright's laboratory and arrives at the following conclusions: The variation of the tuberculo-opsonic index of healthy individuals is very small, and therefore normal serum furnishes a good standard for the comparison of infected persons from day to day. With a diminution of the number of washed corpuscles in the opsonic mixture there is an increase in the amount of phagocytosis. Agglutination of the washed red corpuscles increases the amount of phagocytosis. The tuberculo-opsonic index is the same whether washed corpuscles are used from a healthy or tuberculous individual. If red corpuscles are taken up with serum the amount of phagocytosis is reduced. Serum sealed up in a capsule at room temperature retains its full power, in the case of healthy blood, for at least a week, and in the case of pathologic blood, for a day or two less. Blood capsules left widely open for several hours give very untrustworthy readings. Two practiced observers can count the same slides, and in almost all cases obtain results that do not vary 10 per cent. Duplicate estimations of the tuberculo-opsonic index of tuberculous patients can be performed, the results differing from each other by less than 20 per cent., except in rare instances (1 in 26).

27. **Opsonic Index in Infants.**—Wells, from observations on newborn babies, concludes that a low opsonic index is not diagnostic in children under 1 year old. In infants a low opsonic index is not inconsistent with health, and the child may be thriving well with a declining index. When the opsonic index is low it will rise in response to the stimulus of an inoculation with bacterial vaccine. The healthy breast-fed infant appears to possess no advantages over the healthy artificially-fed child. The anti-bacterial defense in children can not depend on the opsonic content of the serum.

28. **The Experimental Error in Opsonic Index.**—White concludes that, while imperfect mastery of details may cause a greater margin of error than will occur with one more familiar with the technic, when once these details are moderately mastered the error will be insignificant. His own experience as a beginner contrasted with his results to-day, gives a maximal experimental error ranging from 4 to 13 per cent.

29. **Statistics of Opsonics.**—Greenwood considers how far the "opsonic index" is a trustworthy guide in the diagnosis and treatment of disease, which must not be confounded with the question of therapeutic inoculations as curative or prophylactic methods. He concludes that there is no valid evidence that the limits of error do not exceed 20 per cent. of the mean value. The asymmetry of the distributions, so far examined, is so great that, in the case of low emulsions, errors in excess are more frequent than "errors" in defect of the mean. There is reason to hope (but no proof) that with high emulsions the variation may become more symmetrical. He suggests that: (a) high indices should be more closely scrutinized than low values; (b) it is better to work with tolerably thick emulsions, giving an average for the normal serum of not less than 3 bacilli to the cell

33. **Surgical View of Opsonic Method.**—Collier considers that to do the best for their patients surgeons must be clinically associated with the opsonists.

39 *Congenital Hypertrophic Stenosis of the Pylorus; Criticism of Its Pathology in Relation to Treatment E Cautley
40 *Aural Manifestations of Inherited Syphilis M Yearsley.
41 Weak Nervous Children and Arsenic. E F Christin

39. **Congenital Pyloric Stenosis.**—Cautley holds that there is grave danger of ascribing to pyloric hyperplasia the symptoms due to spasm, with or without dilatation of the stomach: that there are mild degrees of hyperplasia compatible with life and giving rise to no serious symptoms; that some of these mild cases depend for their fatal issue on secondary complications which are curable by diet and lavage; that the majority of the cases tend to gradual contraction of the circular muscle and a degree of obstruction which is incompatible with life and only curable by surgical methods. He protests most strongly against delay in adopting surgical measures, as he is convinced that the bulk of the supposed cures of this affection by medical means are really instances of simply pyloric spasm. Great care is essential in distinguishing between spasm and hypertrophy, or many unnecessary operations will be performed

40. **Inherited Syphilis of Ear.**—Yearsley agrees with Hermet and Baratoux' estimate of ear affections in inherited syphilis, viz, one-third. The most important complications are those affecting the labyrinth, which is attacked in two ways, one group having the onset without vertigo, in the other vertigo being a marked feature. In the first form the pathologic condition consists chiefly in a chronic osteitis leading to gradual, more or less complete, occlusion of the cavities of the internal auditory meatus and bony labyrinth. The symptoms and pathologic findings resemble those met with in the tertiary form of acquired disease. The second group is uncommon. The symptoms are best accounted for by an increase of tension due to exudation. When acute, the pressure causes immediate destruction of the labyrinthine nerve endings; when more chronic there is a constantly recurring increase of tension This group resembles the manifestations of secondary acquired disease. The labyrinth is usually attacked between the ages of 8 and 25. Usually ear troubles follow eye troubles. The ordinary treatment of inherited syphilis does not appear to have much effect on the eye troubles. The author has found pilocarpin, given by injection in labyrinthine deafness due to both acquired and inherited syphilis a very valuable agent if used early. In a girl 11 years old, 1/12 grain, (.005) gradually increased to 1/5 grain (.012) daily, resulted in 50 per cent gain in bone conduction in a fortnight

51. **The Suprarenal Capsules in Eclampsia and Nephritis.**—Chirié tabulates in detail the findings in respect to the suprarenals in 12 cases of puerperal eclampsia, 1 of retroplacental hemorrhage, 4 of pregnancy nephritis, 1 of pyelonephritis, 3 of pneumonia, 2 of puerperal infection, 4 of tuberculosis. These findings show the constancy of a notable hyperplasia of the cortex of the suprarenals in puerperal eclampsia, retroplacental hemorrhage and pregnancy nephritis, with considerable hyperplasia of the medulla in many instances. This hyperplasia seemed to be primary, preceding the accompanying hypertrophy of the heart and arterial hypertension.

52. **Prolonged Decalcification in Pregnancy.**—Marquis confirms Bar's assertions in regard to the loss of lime which occurs during pregnancy. It may assume pathologic proportions, revealed by the looseness of the pelvic articulations, the presence of osteophytes and tender spots on the bones, and the high percentage of lime in the blood, urine, and stools. He has recently observed a case of this decalcification commencing in pregnancy but continuing afterward. The painful laxness of the symphysis persisted and the patient was unable to walk. While in the maternity hospital she was given food containing large proportions of lime, and the decalcification was temporarily held in check.

58 *Early Syphilitic Paralysis and Neuralgia. Debove.

57. **Lumbar Appendicectomy.**—Legueu mentions a few cases in which movable kidney apparently caused disturbances which were not cured by operative fixation of the kidney. Appendicectomy later banished the last disturbances. In another case the appendix was removed for two mild attacks of subacute inflammation, but nothing was done for the movable kidney. The disturbances persisting, nephropexy was done and the patient was restored to health. He advocates removing the appendix whenever there is occasion to fasten a movable kidney, and gives an illustrated description of the preferable technic.

58. **Early Syphilitic Paralysis and Neuralgia.**—Debove reports four cases. In the first and second the paralysis affected the seventh nerve with neuralgia in the fifth; in the third case there was paralysis of the seventh nerve, and in the fourth, of the third and seventh nerves with neuralgia in the fifth. These disturbances developed early in the course of syphilis, and the resemblance is striking between them and similar symptoms in tabes. He regards the process as identical in both, a reaction on the part of the meninges, acting on the roots of the nerves. Syphilitic neuralgia and paralysis are therefore signs of incipient tabes, and require energetic treatment.

66 *Primary Sarcoma of Great Omentum (Sarcomes primitifs du grand epiploon) E and R Bonamy

60. **Postoperative Menstrual Cyst Hematomata.**—Dartigues applies this term to the cysts which form on the relics of adnexa. The diagnosis is based on the pains in the hypogastrium, phenomena of general congestion in the region, and a palpable tumor—all these signs recurring with the menses and partially subsiding with them. There is danger that the cyst may rupture or suppurate or induce formation of adhesions with occlusion of the intestines. A few cases are on record, and he reports another, in which prompt operative

treatment restored the patients to health. In a few other cases intervention came too late, and the patients succumbed to septicemia.

61. **Abdominal Fixation of Uterus at the Cervix.**—Delbet and Caraven have examined recently 23 patients treated by this technic between 1896 and 1906. They give an illustrated description of their technic with summaries of the case histories. A few of the women have passed through a pregnancy since without disturbances. Abortion occurred in two cases, but the hysteropexy could not be incriminated in either instance. The absence of adhesions above the internal os allows the uterus to enlarge normally and no complications of any kind were observed. Six of the eleven women who conceived later had been sterile before the operation.

62. **Retroperitoneal Lipomata.**—Proust summarizes 89 cases from the literature. The growths are not malignant, but are liable to become dangerous from their close adhesion to adjacent viscera and their size. Extirpation has given 30 per cent. mortality on account of the necessary resection of sound organs imbedded in the growth.

64. **Nature of Hydatidiform Mole.**—In about 50 per cent. of the cases of chorioepithelioma there is a history of a preceding mole, but only about 10 per cent. of the moles on record were followed by a malignant growth. There is no means of distinguishing a harmless mole from one destined to become malignant. In a number of moles examined by Brindeau all presented the characteristics ascribed exclusively to malignant moles, and yet two of the patients remained in good health and bore healthy children later. Careful medical supervision will reveal the first symptoms of recurrence of the mole, he says. The curette will confirm or exclude the possibility of chorioepithelioma, and hysterectomy then will be in plenty of time.

66. **Sarcoma of Omentum.**—Bonamy adds another to the fifteen cases on record and summarizes the details of each. Only five of the patients survived the operation for a year or more in the twelve cases in which it was attempted. Sarcoma of the omentum is always very vascular and the operative shock is liable to be unusually severe. In only one of the cases was the growth differentiated correctly. It is generally on the median line and develops downward, pushing down the genital organs. The upper limit of the area of dulness is usually concave. The effusion in the abdominal cavity is inclined to be hemorrhagic. The course averages about a year.

73. **Colica Mucosa.**—Cheinisse reviews the literature on the subject of the secretory neurosis which Nothnagel differentiated from mucomembranous enteritis, as there is no inflammatory substratum. Opinions are contradictory in respect to the presence or absence of an anatomic basis; Cheinisse concludes that only prolonged and minute study of the case will decide whether there is inflammation or not. If the trouble is merely mucous hypersecretion of nervous origin, recurring periodically, the stools will be free from mucus in the intervals between attacks.

81 *Supernumerary Mammæ in Axillæ. (Achselhöhlenbrüste bei Wöchnerinnen.) F. Kayser.

75. **The Formed Elements in the Blood in *Prognosis of* Puerperal Affections.**—Gräfenberg has been conducting research in this line for some time, and thinks that it is important to take note of the leucocyte curve, the curve of the small lymphocytes, and, above all, of the number of nuclei. The findings are especially instructive in gonorrheal affections. He relates extensive experiences which show that the curve of the number of nuclei was constantly downward in the cases which ended fatally, while it was as constantly upward in the favorable cases.

76. **Origin of Endothelioma.**—Kworostansky relates the microscopic findings in cases of endothelioma of ovaries or tubes in connection with the case histories. They show that endothelioma develops in consequence of mechanical injury—pressure and rupture, or of chemical injury—necrosis of the tissues under pressure and absorption of the decaying tissue elements into the blood. When the reparatory process is once started it may continue beyond bounds and induce the formation of a neoplasm. The peritoneum is a favorable site for such a process. In one case there was considerable neoformation of endothelium in certain vessels of the peritoneum which had been compressed by a hematoma in the broad ligament causing an inflammatory reaction.

77. **Hemorrhage in Chronic Metritis.**—Ahreiner refers to the metritis of the parenchyma alone, the mucosa being intact, of which he relates five cases with the microscopic findings in the uteri removed on account of total prolapse or uncontrollable hemorrhage. The main cause of the hemorrhage must be sought outside of the uterus. The bleeding occurs more readily when the uterine vessels are sclerotic, but the latter alone is not able to induce hemorrhage without the general cause, inducing congestion in the region.

81. **Mammæ in the Axillæ.**—Kayser reported a few years ago cases of tumors observed in the axillæ of women. He here describes six more cases, all in puerperæ. The women were not much annoyed by the tumors although they increased in size during the menstrual periods and became large during the puerperium. He regards them as supernumerary mammæ, evidently an atavistic anomaly. He encountered these six cases in the course of eleven months; all but one of the patients were i-paræ. He has found nineteen similar cases in the literature.

88 *Periodical Vomiting. (Das periodische Erbrechen.) J. S. Arkawin.

82. **Septic Arteritis in Children.**—Baginsky discusses the literature on aneurisms in children, and reports a case of aneurism of the abdominal aorta and subclavian artery in a girl under 8. The eye findings suggested inherited syphilis, but the symptoms indicated septic infection. Examination under chloroform revealed aneurismal enlargement of the abdominal aorta and other signs indicated streptococcus arteritis with a

tendency to enlargement in various arteries, thrombosis and obliteration of the vessels.

83. **Localization of Brain Tumors in Children.**—Klose reports a case in which a sarcoma developed in the cerebellum after two severe blows on the head. In the course of four years pronounced psychic disturbances became manifest, but there were no characteristic focal symptoms and no cerebellar ataxia. Radioscopy showed a shadow in the frontal lobe which was assumed to be cast by a tumor. No tumor was found at the operation, but the third ventricle was much enlarged, with its contents under high pressure, and this condition had been responsible for the shadow cast. He warns that this physical phenomenon in the child brain under certain conditions may simulate a tumor in the Roentgen picture. The case also teaches that internal hydrocephalus may occur early and be intense, with a tumor in the cerebellum, and may complicate the topical picture in the most deceptive manner and induce rapidly progressive mental deterioration. The trephining in the case reported did not cause any motor disturbances notwithstanding the extensive destruction of the right temporal lobe. In another case of hydrocephalus benefit was derived from repeated lumbar puncture, the boy recovering consciousness even the last time and saying that he felt better, but then he suddenly succumbed. Klose concludes his monograph with the remark that pediatrists, more than anyone else, are interested in efforts to change the present merely palliative treatment of brain tumors in children into the true causal-surgical treatment, which improved radiographic technic will immeasurably promote. Pediatrists and radiologists should work side by side in exploring this interesting borderland.

84. **Relations Between Lactation and Menstruation.**—Jacobius found 79 menstruating in 180 women examined about the sixth month after childbirth. The type of menstruation was not quite normal, but no interference with the nursing capacity was observed in any instance. The women were under constant control and prizes were given for the best "nurser." The children increased in weight, even with the most profuse menorrhagia, in nearly every instance. The majority of the children showed transient disturbance, restlessness, or a tendency to diarrhea or dyspepsia, and in a few cases they vomited the milk, but these were all transient disturbances and the children thrived.

85. **Retention of Capacity for Production of Milk by Non-Nursing Mothers.**—Jacobius has been able to have women nurse their infants, even after the child has not been nursing for several weeks, and even in women who have not nursed the infant at all after its birth, the interval ranging from three to twenty-six days. Good results were obtained with a tube fastened to an ordinary rubber nipple; which the mother could use herself, sucking the end of the tube. The infants never seemed to suffer from the composition of the milk after the long suspension.

88. **Periodical Vomiting in Children.**—Arkawin has observed four cases, in all of which the patients had neuropathic inheritance with a tendency to obstipation. The vomiting ceased when the intestinal functions were regulated.

89. **Antitryptic Power of Human Blood Serum.**—Brieger and Trebing found that normal blood serum contains sufficient antibodies to inhibit the digesting action of a 1 per cent. solution of trypsin on the Loeffler plate in the proportion of 1 to 3. A distinct reaction still occurs in a strength of 1 to 4, in a few cases 1 to 6. Twelve patients with diabetes examined showed a loss of inhibiting power in 7, and normal conditions in the others; about the same findings were obtained in 4 patients with tuberculosis, in 8 with non-malignant stomach affections, 6 with various other affections, and in 4 with syphilis. On the other hand, the inhibiting power of the serum was very much increased in each of 35 patients with cancer, as much as from 1 to 10 and 1 to 20 in the majority. The same findings were obtained in 8 cases suspicious of carcinoma. In 3 cases in which a cancer had been removed a year or more before, the antitryptic action approximated the normal type, as also in 6 cases of non-malignant tumors. This trypsin reaction may aid in the differentiation of carcinoma, although the reaction is not specific for cancer but merely denotes considerable inhibiting power in regard to trypsin, which is observed also in severe blood affections. The authors are now engaged in research as to the possible influence on this reaction of ingestion of trypsin.

90. **Pubiotomy.**—Kroemer reports the experiences with pubiotomy in Bumm's service at the Charité, Berlin—a total of 53 cases. Nine of the women have passed through a second pregnancy since. The results confirm the advantages of the operation; the great difficulty is the selection of the proper cases for this technic. The sawing of the bone is not the danger for the woman, but the too rapid passage of the head. Every effort must be made to have the birth proceed spontaneously, and pubiotomy should be applied only when vigorous uterine contractions give prospect of spontaneous delivery. Complications, such as prolapse of the cord, stricture of the soft parts, infection and eclampsia, contraindicate pubiotomy. Recent examination of 34 of the women shows them free from disturbances in gait, and with unimpaired earning capacity. The cicatrix in the bone seems to be permanently flexible in all but five women. This allowed the pelvis to enlarge spontaneously in all but one of the 9 childbirths later. He thinks that these pelvis-enlarging operations will tend to reduce the number of obstetric operations. Relying on pubiotomy, the natural forces can be utilized to their last possibility.

98 *Operative Treatment of Emphysema of the Lung. L. Müller.

97. **Occult Blood in Stools and Stomach Content in Diagnosis of Cancer.**—Isler reviews forty-eight articles that have been published in Germany on this subject since Boas first called attention to the diagnostic importance of invisible blood in the feces. Invisible hemorrhage never occurs, it seems, in purely nervous stomach affections, but may be found in case of insufficiency of the stomach, due to cancer or non-malignant stenosis. The constant positive blood reaction in the stools, with still good motor functioning on the part of the stomach, no free hydrochloric acid and no lactic acid, is presumptive of the presence of cancer.

98. **Operative Treatment of Emphysema of the Lung.**—Müller has found only eleven articles on this subject, although Freund's first communication was published exactly fifty years ago. Good results have been obtained in the few cases adapted for the operation in which it has been done, as has been already mentioned in these columns.

105 **Diagnosis and Treatment of Psychoses in Children.**—Raecke discusses catatonia, melancholia and other psychoses as occurring in children Catatonia has been observed before the age of 7, but generally does not appear until after the eleventh year. He regards it as the most important psychosis of childhood External causes play only a subordinate rôle in its development; in most cases there is an inherited nervous taint The preliminary stage of depression may be mistaken for melancholia at first. Treatment of all acquired psychoses in children is symptomatic. The little patient should be kept in bed with strict supervision Serious attempts at suicide are not rare among such children Excitement is best combated by prolonged warm baths and warm wet packs. The food should be light, nourishing and given at short intervals with the stomach tube, if necessary. It is important to keep constant control of the weight with the scales. After recovery, rest and freedom from excitement must be ensured and a healthful and non-strenuous occupation selected in later life.

107. **Pancreatic Diabetes and Parabiosis.**—Forschbach refers to Sauerbruch's recent reports on parabiosis, as he calls the union of living animals by a permanent organic joining of the abdominal cavities. He has thus united an animal with diabetes following removal of the pancreas with another healthy animal. By the parabiosis the tendency to diabetes of the pancreatectomized animal was reduced or entirely abolished.

108. **Lung Affections Following Trauma.**—Baumann and Groedel relate the history of a case of "contusion pneumonia" in a young man. In a second case the Roentgen findings indicated the same, but autopsy disclosed that there had been no pneumonia The apex was compressed by a large epipleural hematoma, and the first rib was fractured. The injury was received while wrestling, and the young man complained that something had broken in his right shoulder. The pains were ascribed to rheumatism by a physician, and the patient returned to work for a time. The hematoma simulated infiltration of the apex in the Roentgen picture and it also concealed the fracture of the rib.

111. **Quinin in Syphilis.**—Napp first tests the tolerance of the patients for quinin for two or three days, and then makes an intravenous injection of quinin, injecting from 0.5 to 0.8 gm. (7½ to 12 grains) for two days and then every second day. He follows Lenzmann's technic and is convinced that this treatment of syphilis has a promising future. He has applied it in twenty-two cases as he relates in detail, the results confirming the efficacy of quinin alone without specific local measures. The by-effects were slight and had all vanished in two minutes after the injection. None of the patients experienced any by-effects in the ears, although they always had them when quinin was taken by the mouth.

114 **Early Operation in Severe Acute Cholecystitis.**—Riedel calls attention to the unreliability of statistics in regard to the mortality of gallstone affections When physicians are accustomed to refer all patients with inflammatory abdominal processes promptly to the surgeon, acute cholecystitis is seen to be a severe and threatening affection in a large proportion of cases. When the gall bladder is distended it should be removed, he says, before it bursts, or before a concrement in the neck of the bladder or in the cystic duct is forced into the common bile duct. Mild cholecystitis should be treated conservatively until the diagnosis is certain. If the general condition is good, an operation should then be proposed, as severe cholecystitis may develop any day. Out of 111 patients seen in 1905-6, not less than 6 were moribund when first seen, and 2 others were on the verge of perforation—all were suddenly developing acute cases. He thinks that the lessons learned from appendicitis apply also to cholecystitis.

115. **Prostatectomy Under Local Anesthesia.**—Lanz comments on the precarious condition of many patients with hypertrophy of the prostate. In 80 cases in his practice two of the patients died the night before the proposed operation The slightest intervention in such cases is liable to be fatal. He regards perineal prostatectomy as altogether too severe an operation, and for two years has been using exclusively the transvesical technic, as much safer and quicker. General anesthesia is contraindicated in these old, more or less septic patients with their tendency to pneumonia. Lumbar anesthesia has rendered good service in twelve cases, but even this is liable to injure the kidneys, and he has lately found that the operation can be done with local anesthesia alone. In nine cases the suprapubic cystotomy was done under infiltration anesthesia with a 1 per cent. solution of cocain with a few drops of suprarenal extract. The prostate was easily shelled out without any further anesthetization; he was surprised at the absence of pain. Two other patients were so debilitated that he performed the operation in two sittings. The prostate was shelled out without any anesthetic, two days after the cystotomy, in one case; in the other the enucleation was not done for a week after the cystotomy. The patients complained only of the pressure of the surgeon's hand on the symphysis; there was no actual pain in the bladder or rectum. He gives a little brandy before the operation, and suggests that possibly the pronounced uremic condition may have cooperated in inducing this remarkable tolerance. In any event, the enucleation of the prostate could be rendered painless by an opium suppository in the rectum with local application of cocain, injected under control of the forefinger in the bladder. He would not advise operating at two sittings in ordinary cases, but only in the exceptional cases which are still considered as beyond relief or burden the conscience and throw discredit on the statistics of operations. He denounces in vigorous terms the use of the catheter, comparing it to probing a wound; the catheter signifies as a rule the end or the beginning *of the end* Instead of using the catheter in cases of enlarged prostate he advocates transvesical prostatectomy as the routine procedure. Without general anesthesia it is no more dangerous than the use of the catheter, while it has the advantage of permanently curing the patient.

124 Atelectasis (Lungenatelektase.) J. Pelser.

123. **Causes of Greater Consumption of Matter in Childhood.**—Kassowitz has been making an extensive study of metabolism and catabolism in children in comparison with adults. He shows that the consumption of matter is influenced by various causes, and that the growth of the children is not such a preponderating factor as generally assumed. Among the other causes are the thermostatic function and the fact that each organism consists of two components, which are entirely distinct: the living, assimilating protoplasm and the non-vital elements and reserve substances. In the young the protoplasm preponderates, but with advancing years the metaplasm—the cellulose, starch, wood fiber, fat, silicates and other organic and inorganic deposits in plants, connective tissue, cartilage and elastic fibers, fat, lime and other organic and inorganic deposits in animals. This fact is sufficient to explain the active metabolism in young individuals aside from other considerations.

126. **Apparent Enlargement of the Heart.**—Herz believes that enlargement is frequently diagnosed when in reality it does not exist. It can not be too often reiterated, he asserts, that the assumption of heart disease is an important factor in producing disease in a previously sound heart and vascular system. He reviews the conditions liable to simulate enlargement of the heart. When for any reason the heart lies more horizontally, it always slides toward the left; the area of dulness and the apex beat suggest enlargement, and a systolic murmur corroborates this. These phenomena are probably caused by the kinking of the heart in respect to the ascending aorta and the eddy in the blood at the point of the kinking. The most common cause of this horizontal attitude of the heart is the pushing up of the diaphragm. The heart slips toward the left no matter whether the right or left side of the diaphragm is lifted. Many causes may push up the diaphragm, and it may induce a number of subjective symptoms and even lead to extrasystoles. An unduly long ascending aorta or a stooping attitude may favor the sliding of the heart toward the left. The displaced apex may return to its normal place when the patient is made to stand up straight as for a military salute. Malformation in the thorax may also simulate a dilated or hypertrophied heart, especially in persons who work stooping over, copyists, dentists, draftsmen and others. The abnormal contact of surfaces in these conditions causes peculiarly marked subjective symptoms. In case the muscles are unusually well developed while the chest is deep, the area of cardiac dulness may extend beyond the maxillary line and suggest hypertrophy. In obese persons it must not be forgotten that the dulness is the enlarged acoustic shadow of the heart, which is exceptionally far below the surface in these persons.

127. **Treatment of Uric Acid Diathesis.**—Rosenfeld's research and experience show that addition of sugar to a diet containing purin causes an increase in the amount of uric acid eliminated. He advises a few tests of the metabolism for each patient, to regulate the diet in accordance with the findings. In respect to medication he advocates the continuous use of urea. It limits the production of uric acid, he declares, and keeps the uric acid in the urine well dissolved. If the patient urinates in a cone of filtering paper the paper will be covered with granules of uric acid in extreme cases, but if these patients are taking daily from 10 to 15 gm. (150 to 225 grains) of urea the filter will be free from crystals. In one case the patient had clear urine under the urea treatment; it was then suspended for eight weeks, and 105 grains of uric acid crystals were collected on the filter in this period. On resumption of the urea the elimination of undissolved uric acid ceased at once. The urea causes no inconveniences of any kind, he says, not disturbing either the stomach or kidneys. Its only fault is that its action ceases with its discontinuance. He also ascribes great importance to glycerin. He does not attribute any concrement-expelling power to it, but believes that it washes out the uric acid retained in the urinary canals, not deposited, and that it arrests the pains induced by concrements in the kidneys. He prescribes it in the dose of 150 gm. for a man weighing 75 kilograms; that is, 2 gm. per kilo (about 14 grains for each pound of weight). The entire dose of 150 gm. is dissolved in tea, Seltzer water or milk, and taken in four portions at two-hour intervals. This dose is repeated on one day every fourth or sixth week, and in the intervals 10 or 15 gm. of urea are taken every day. He regards this glycerin-urea treatment as acomplishing all that can be expected until we discover some means of dissolving the concrements themselves.

128. **Suction Hyperemia in Urology.**—Frank has treated 60 patients with buboes by application of a cupping glass to induce suction hyperemia, and reports good results. He gives an illustration of the large cupping bell he uses; it fits over the region and can easily be applied by the patient himself. It is applied for twenty minutes every two hours, with or without incision. The pain of gonorrheal joint affections was always promptly arrested by constriction hyperemia, combined with superheated air. Several cases are described of genital tuberculosis in young men in which remarkable benefit was obtained with the cupping bell. In two of the cases no other measures except a mutilating operation could have been considered. He believes that artificially induced hyperemia, applied in time, will render the treatment of genital tuberculosis much more conservative and promising than has been the case hitherto. Small foci in the prostate, and perhaps also the seminal vesicles, are favorably influenced and heal under suction applied to the testicles. The method is also of service in hastening the healing of fistulous passages.

133. **Transplantation of Joints.**—Lexer's experiences with restoration of joint function by transplantation of part of a joint from an amputated limb have been previously mentioned in these columns. Even if only a hinge joint can be supplied, the functional results are excellent. One patient was a man of 38 with sarcoma of the tibia requiring resection of the upper third and of the articular cartilage. A corresponding piece from the tibia of a limb amputated from another man on account of senile gangrene was introduced in its place, and in three months the patient was using the leg almost normally, with no shortening. In another case the second toe from an amputated limb replaced a finger removed on account of chondroma. In a third, a girl of 19 had right-angled synostosis of the left knee after suppurative osteomyelitis. After resection of a wedge from the joint a gap was left of more than two inches between the tibia and femur. The knee from an amputated limb was implanted in this gap and the projecting epiphyses nailed to the bones. The patellar ligament was sutured to the periosteum and a fenestrated plaster cast applied. In the fifth week the *x*-rays

showed callus growing over the edges of the implanted epiphyses, and the leg was exercised. The patella grew to the bone beneath, and in the third month the flap was lifted and the patella was removed. Vital processes could be seen in the implanted tissues. Normal passive movements are possible but active movements are still defective as important muscles are lacking. Recently he raised the entire flap for the second time, and a piece of the tunica vaginalis, nearly six inches square, taken from a hydrocele being operated on at the same time, was transplanted with the raw side on that of the flap to which it was fastened. The upper edge was sutured to the periosteum over the upper epiphysis, and in such a way that a fold forms as the joint is used The flap was then replaced without further fastening of the transplanted serosa He thinks that this technic supplies a sufficient substitute for the capsule of the joint A piece of omentum might be used for the serosa graft, and it might be implanted at the first operation or as a preliminary before the operation. He has never tried to implant an entire unopened joint in an adult for fear of necrosis, but he has done this on the knee of a child, transplanting the entire capsule and epiphyses, with excellent results to date He does not approve of implanting substances foreign to the body, like celluloid, as they induce unwished for reactions.

134 **Suprarenals and Rachitis.**—Stoeltzner presents arguments to prove that functional insufficiency of the suprarenals is the predominating factor in rachitis and osteomalacia. In animals and in man, he says, domestication, living indoors, is what paves the way for rachitis The degeneration of the suprarenals may be the result of generations of unphysiologic minimal demands on the functioning of the striated musculature.

141 *Successful Suggestive Treatment of So called Uncontrollable Vomiting of Pregnancy (Suggestiv Behandlung der Hyperemesis gravidarum) F. Schulte

141. **Suggestion in Treatment of Vomiting of Pregnancy.**—Schulte states that at the clinic in Giessen, 18 cases of uncontrollable vomiting have been observed, and the patients were cured by suggestion Various measures were used, all for the suggestive effect In every case there was pronounced hysteria or nervousness accompanied by enhanced irritability of the sensory nerves. The patients were put to bed, on a liquid diet at first, sometimes with alimentary enemas; lavage of the stomach was done occasionally to impress the patients One of the best measures was the suggestion of retroflexion of the gravid uterus. A sham correction of the retroflexion was then carried out and a pessary inserted for a few days. All the patients responded with prompt arrest of the hitherto incoercible vomiting. It was never found necessary to interrupt the pregnancy. In one case retroflexion actually existed and the vomiting ceased after it was corrected, but recurred when the pessary dropped out of the vagina, although the uterus was then in anteflexion. The vomiting ceased again when the pessary was replaced. Three of the patients had recurrence of the vomiting at different pregnancies, cured each time by the same measures. One patient had a recurrence of the vomiting after her return home, but suggestion by letter that the vomiting would cease in three days, when the menstrual period was over, proved effectual. It seems evident that the hyperemesis which is observed without an appreciable affection of any internal organ is a purely psychogenic symptom induced by the pregnancy, and consequently, curable by suggestion.

143. **Constriction Hyperemia in Meningitis.**—Stursberg is assistant at Schultze's clinic at Bonn where he has been studying the influence on the cerebrospinal fluid of application of an elastic band to the neck. The results are not encouraging for use of this measure in meningitis.

152. **Clinical Importance of Inflamed Tonsils.**—Muck regards the tonsils as responsible for the recurrences of articular rheumatism, etc. In 50 cases of chronic tonsillitis, with plugs and pus in the tonsils, he found an apical affection in 27 per cent He has devised a simple aspirating contrivance for evacuating the contents of the crypts in the tonsils. He calls it the "tonsil exhaust," and relates two cases to show its advantages for diagnosis and treatment, with an illustration of the aspirator. Recurring acute articular rheumatism vanished permanently after its application in these cases.

153. **Idiosyncrasy to Eggs and Alleged Meat Juice Preparations.**—Landmann has a patient, a man of 35, who has a marked idiosyncrasy to eggs, but is otherwise healthy. Ingestion of the slightest trace of egg albumin causes serious distress. The same distress followed the ingestion of a certain "meat juice" preparation. This experience was incomprehensible until a recent exposure of the meat juice preparation revealed that it was composed of meat extract and egg albumin.

155. **Brain Tumors.**—Knapp reviews recent progress in the diagnosis of brain tumors, citing concrete examples He advises puncture of the brain to confirm or correct the diagnosis, repeating it at various points to determine the extent and nature of the tumor, the location, blood content and eventual secondary softening. During the operation several pathologists in the operating room itself should be constantly examining the character of the excised scraps of tissue in turn until, all around the tumor, the surgeon is working in sound tissue.

156. **Typhoid Bacilli in Blood in Non-Typhoid Affections.**—Busse was able to cultivate typhoid bacilli from the blood of four patients with a severe infectious disease, but no signs of typhoid during life or at autopsy. One was a patient with pneumonia, the others had miliary tuberculosis or phthisis. He thinks that such cases would be more numerous if sought for. The patients had probably been bacilli carriers. The cases show that typhoid does not develop in these bacilli carriers even when the bacilli get into the blood. They teach further that positive findings in respect

to typhoid bacilli in the blood are not decisive as to the presence of typhoid fever.

159. **Suction Hyperemia in Diseases of the Middle Ear.**—Stimmel has treated chronic otitis media in thirty cases with Bier's suction apparatus with marked improvement in the hearing in seven cases. The pus and fetor vanished and the mucosa healed. In fifteen other cases marked improvement was observed, but the present results are not known. In two other cases the process was evidently tuberculosis, but improvement was obtained. The ear affection had lasted for from two years to fifty, rebellious to all treatment. The suction bell was applied for from two to thirty-five times, at two or three day intervals, at first for ten minutes, and never for more than fifteen. He prefers a suction bell with a diameter of 5 cm., the suction only strong enough to cause distinct swelling of the ear, never pain in the interior of the ear. He never observed disagreeable by-effects. It is surprising, he says, the amount of pus or serum found in the ear after the suction. In very painful cases of furunculosis of the ear, a constricting band applied for six or eight hours during the day gives relief, but arteriosclerosis and enlargement of the tonsils contraindicate this measure. Caries and cholesteatoma also contraindicate suction treatment in middle ear disease.

178 *Functional Kidney Tests. (Zur funktionellen Nierendiagnostik.) R. Lenk.

165. **Gangrene of the Extremities in Typhoid Fever.**—Biron has found 11 cases of this complication of typhoid in Russian literature, and adds another to the list. With two exceptions the patients were between 18 and 25. In his patient the gangrene of the right foot and thigh developed at the commencement of the third week of a mild typhoid fever. He ascribes the gangrene to thrombosis due to arteritis or spasm of the vessels. Both the typhoid bacilli and their toxins may participate in the production of the arteritis. The thrombosis may be favored by disturbance in the general circulation from myocarditis, paralysis of the vagus center, disturbance in the automatic ganglia of the heart or in the coronary arteries or by increased coagulability of the blood and lowered resistance of the tissue cells from toxic and trophic influences. He remarks in conclusion that arteritis not leading to gangrene is frequently overlooked, but undoubtedly contributes to the later development of arteriosclerosis, aneurism, etc., after typhoid and other infectious diseases.

174. **Serum Diagnosis of Syphilis.**—This communication was presented at the recent congress for internal medicine at Vienna, and in it Wasserman announced that the serum diagnosis of syphilis, by the complement-binding method with aqueous or alcoholic extracts of syphilitic organs, is reliable in the clinic, and is now ripe for general adoption.

178. **Functional Kidney Tests.**—Lenk reports from Hochenegg's clinic at Vienna a few cases of kidney affections in which the phloridzin test gave misleading findings, sometimes indicating normal conditions when the kidney proved to be seriously diseased, while in other cases the test indicated advanced disease when the kidney proved to be functionally capable as soon as reflex disturbance subsided.

184 *Apparatus for Overpressure. (Einfacher Apparat zur Ueberdrucknarkose.) M. Tiegel.

179. **Sensibility of the Abdominal Organs.**—Ritter reports extensive research on dogs and rabbits, which shows that the abdominal organs are not so free from sensibility as Lennander announced. The ligation of the vessels in the abdominal cavity seems to be the touchstone for the degree of sensitiveness.

180. **Treatment of Acute Suppurative Osteomyelitis.**—Rolando has treated a number of patients between 6 and 18 with hematogenous osteomyelitis, and has obtained the best results by trephining at the lowest point of the suppuration, thus allowing free escape to the pus. A preliminary skiagram will determine the exact location of the focus. It is unnecessary to open up the focus, he says, further than to allow its evacuation by the trephine.

182. **Retention Catheterization of Ureters in Bladder Affections, Etc.**—Cardenal writes from Madrid to endorse the advantages of leaving a retention catheter in each ureter when it is advisable to keep the bladder dry for a few days after operations, removal of stones, enucleation of the prostate, etc. His experience shows that the catheters can be left for nine days without complication, and he thinks that they might be left for two weeks. The results of intravesical intervention are much better when the bladder can thus be kept dry to permit primary healing.

184. **Apparatus for Overpressure.**—Tiegel's apparatus is illustrated as he has used it in a number of operations on the lungs, heart or esophagus. There was no collapse of the lungs. The patient kept on breathing quietly and regularly although the pleural cavity was opened for more than an hour in some cases. The apparatus consists merely of a small mask, a rubber balloon, the tank of oxygen or compressed air, and a water jar. There is nothing to interfere with the work of the anesthetist or operator.

185. Delivery by the "Uterus-Abdominal Wall Fistula."—Sellheim has been seeking for a technic of extraperitoneal incision of the uterus which would be safe even for infected cases. He thinks he has accomplished this by what he calls "*Uterusbauchdeckenfistel*," which aims to deliver the febrile parturient through a small opening in the abdominal wall, the abdominal cavity and the pelvic cellular tissue being thoroughly protected. The main point is to incise the abdominal wall and the wall of the uterus at a point where they correspond, and where this correspondence can be maintained even during involution of the uterus. This is possible with a median sagittal incision immediately above the symphysis. The parietal peritoneum is sutured carefully to the edges of the incision in the skin. The abdominal cavity is shut off by suturing the parietal and uterine peritoneum. The uterine peritoneum and the reflection over the bladder are mobilized on each side, and the edges sutured to the skin around the incision, where the parietal peritoneum is already fastened. The bladder is pushed to one side. By carefully incising the wall of the uterus the outer layers can be seized and brought up outside the cutaneous incision. After opening into the cavity of the uterus and wiping the edges of the wound, they are seized with forceps and drawn outside the abdominal wound. The edges of the uterine wound thus drawn out are pulled down over the edges of the abdominal wound on all sides and held with forceps. The tissues here are so elastic that the child can be extracted without their tearing. After the extraction of the child, the turned-over edges of the uterine wound are fastened to the skin. The fistula rapidly heals. In the case described, by the fifth day nothing was left of the opening except a hole 5 cm. in diameter, surrounded by a ring of uterus wall about 1 cm. thick. The patient was allowed to get up early, even although the uterine cavity was secreting considerably and there was slight superficial suppuration at the edge of the fistula. The uterus wall was sutured the eighteenth day, and the patient was discharged with restored working capacity the fifth week, with a healthy child.

187. Childbirth with Double Uterus.—A iii-para, 24 years old, was in labor for a week. Finally the contractions became more vigorous and the child was rapidly expelled. Manual loosening of the placenta led to the discovery of a double uterus; the walls were remarkably thin and the second uterus had participated in the formation of decidua; its cervix was also dilated.

188. Convoluted Uterus.—Bossi has found in a number of cases that dysmenorrhea, nervous disturbances and sterility are the result of the curving of the cervix of the uterus back on itself, thus presenting the shape of a convoluted seashell. The condition causes a tendency to painful menstruation, leucorrhea, hysteria and chloroanemia in the unmarried, and endometritis and sterility in the married. He treats it by cutting off the curved part of the cervix. He sometimes performs a plastic operation or uses his intrauterine pessary. Experience with 200 cases has shown, he says, that this pessary answers every purpose while it causes no disturbances even when left in place for 15 or 20 days.

190. Stimulating Effect of Rectal Injection of an Infusion of Sodium Saccharate.—Schücking's favorable experiences with infusion of sodium saccharate have been mentioned in The Journal. When haste is not necessary, rectal instillation is preferable. The effect on the vascular system and intestine of rectal infusion of a 0.3 per cent. solution of sodium saccharate and 0.7 per cent. salt solution is remarkable in septic conditions. It raises the blood pressure and improves the circulation in general while putting an end to atony of the intestine in puerperal peritonitis without inducing a tendency to diarrhea. He allows only a drop at a time to enter. When designed to stimulate the vascular system, he instils the fluid an hour at a time, but in case of intestinal atony, he keeps up the instillation for 24 hours, using in this time 2 or 3 liters of the fluid. The sodium saccharate seems to have a direct influence on the metabolism and the functioning of the musculature of the bowels.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Outlines of Physiology. By Edward Groves Jones, A.B., M.D., Professor of Surgery in Atlanta School of Medicine, and Robert Grier Stephens, A.B., M.D., Instructor in Physiology in the Atlanta School of Medicine. Second Edition, Revised. Pp. 383, with Illustrations. Price, $1.50. Philadelphia: P. Blakiston's Son & Co., 1908.

A Manual for Midwives. By C. Nepean Longridge, M.D. (Vict.), F.R.C.S. (Eng.), M.R.C.P. (Lond.), Late Resident Medical Officer at Queen Charlotte's Hospital. Cloth. Pp. 309, with Illustrations. Price, $1.40. Philadelphia: P. Blakiston's Son & Co., 1908.

A Short Practice of Midwifery. By Henry Jellett, B.A., M.D. (Dublin University), F.R.C.P.I., Ex-Assistant Master, Rotunda Hospital. Fifth Edition, Revised. Cloth. Pp. 645, with Illustrations. Price, $4.20 Philadelphia: P. Blakiston's Son & Co., 1908.

The Newer Remedies. By Virgil Coblentz, A.M., Phar.M., Ph.D., F.C.S. Professor of Chemistry in Columbia University, Department of Pharmacy. Fourth Edition, Revised and Enlarged. Cloth. Pp. 133. Boston: The Apothecary Publishing Co., 1908.

Diseases of the Nervous System. By H. Campbell Thomson, M.D. (Lond.), F.R.C.P., Dean of and Medical Tutor in the Middlesex Hospital. Cloth. Pp. 480, with Illustrations. Price, $2.75. Chicago: W. T. Keener & Co., 1908.

Meat and Food Inspection. By Wm. Robertson, M.D., D.P.H.F.P.S., Lecturer on Public Health, Royal College for Surgeons, Edinburgh. Cloth. Pp. 372, with Illustrations. Price, $3.50. Chicago: W. T. Keener & Co., 1908.

Electrical Treatment. By Wilfred Harris, M.D., F.R.C.P., Physician to the Department for Nervous Diseases, St. Mary's Hospital. Limp Cloth. Pp. 383, with Illustrations. Price, $2.25. Chicago: W. T. Keener & Co., 1908.

Insomnia and Nerve Strain. By H. S. Upson, M.D., Attending Neurologist to the Lakeside Hospital, Cleveland, Ohio. Cloth. Pp. 142, with Skiagraphic Illustrations. Price, $1.50. New York: G. P. Putnam's Sons, 1908.

Address

THE COORDINATION OF SINGLE MUSCULAR MOVEMENTS IN THE CENTRAL NERVOUS SYSTEM.*

C. E. BEEVOR, M.D., F.R.C.P.
Physician to the National Hospital for the Paralyzed and Epileptic.
LONDON, ENG.

It is with a deep sense of the great honor which has been bestowed on me that I come before you, and I can assure you that I appreciate very much the invitation which your chairman sent me to give an address before the Section on Nervous and Mental Diseases of the American Medical Association. I must confess to feeling somewhat disconcerted at the imposing names of professors who have preceded me, and I must crave your indulgence if I fail to attain the high standard which they have set.

In choosing a subject it seemed to me that the great value of international meetings or of the custom of inviting members of another country to give addresses consists largely in the opportunity it offers of bringing forward subjects which may not have engaged the attention of the members of the profession over here and may thus be the means of directing their thoughts into fresh channels. For this reason I have chosen the subject of the coordination of muscular movements in the central nervous system, as it is one of great importance from a practical as well as from a theoretical point of view and one which perhaps has not received the amount of attention which it merits.

First, it will be necessary to state what is meant by a muscular movement, what the different classes of muscles are which take part in any particular movement.

By the term muscular movement I mean the single movement of one joint, such as flexion of the thumb, or of several similar joints, such as flexion of all the fingers and the thumb as in grasping; I do not refer at present to such a combination of movements as are involved in the act of walking. Now what are the different classes of muscles which may take part in any particular movement, such as that of flexion of the fingers and thumb in the act of grasping? We have first the muscles which do the work, viz., the flexors of the fingers and thumb and which are called the prime or principal movers. We also have the antagonists to the movement, i. e., those muscles which produce the movement which is the opposite to the one we wish to perform, viz., the extensors of the fingers and thumb. Furthermore, we have to notice that the prime movers, the flexors of the fingers and thumb in their course from their origin in the forearm to their insertion into the phalanges pass over the wrist joint, and it will be evident that after these muscles have flexed the thumb and fingers they will also tend to flex the wrist.

This movement of flexion of the wrist, however, is not wanted, and it would be very awkward if, whenever we grasped an object firmly, the wrist would persist in flexing. How is this difficulty to be overcome? It is done by bringing other muscles into action which will prevent the wrist being flexed, and the muscles which can do this are the extensors of the wrist; so that whenever we perform the movement of grasping, the extensors of the wrist contract and their tendons on the dorsum of the wrist can be seen and felt to become tight. These muscles are called synergic muscles because they work with the prime movers whenever these muscles pass over two joints, and they neutralize the action of the muscles which is not required.

Other muscles which take part in simple movements are those which we may call fixation muscles, as they fix and prevent any movement in the joints intervening between the joint, in which the movement required is being performed, and the trunk. Taking the movements of the fingers as an example, it is found that in flexing the fingers against resistance, when the forearm is in the position of supination, the tendency of the resistance, if strong, is to overcome and extend the wrist and the elbow, and in order to counteract this tendency the flexors of the wrist and the flexors of the elbow—the biceps, supinator longus and other muscles —contract to fix the wrist and elbow joints. We have, therefore, the following classes of muscles which may take part in a movement: 1. Prime or principal movers. 2. Synergic muscles. 3. Fixation muscles. 4. Antagonists.

PRIME OR PRINCIPAL MUSCLES OF MOTION.

Taking first the prime or principal movers, we have to take into account in performing a movement whether muscles forming the prime movers all contract together, or whether there is any sequence, and whether the same sequence is always preserved. It is not easy to find a group of muscles in which it can be ascertained which particular muscle is contracting first. But in supinating the forearm the two chief muscles are the supinator brevis and the biceps, and if no work is being done it is possible to supinate the forearm without producing any contraction of the biceps.

Another example of this is shown in flexing the elbow. If this joint be flexed lifting only the weight of the forearm, the biceps is seen and felt to contract without any action of the supinator longus, and the joint can thus be kept in a position of flexion with the forearm at right angles to the vertical humerus.

Another group of muscles which I have lately observed is that of the flexors of the hip. Some of the muscles such as the psoas and iliacus, are too deep and can not be seen or felt to contract; but there are two, the sartorius and the rectus femoris, which are easily seen and felt. Besides flexing the thigh on the trunk, they will also flex the trunk on the thigh, if the latter be the fixed point, and it is in this movement that a differentiation can best be made out.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

To show this the person should stand erect on one leg and have the other resting on a chair, with the knee and thigh flexed. The person should incline slightly forward, so as to bring the center of gravity in front of the foot on which he is standing. On then inclining backward, so as to shift the center of gravity behind the foot, the flexors of the hip of the leg resting on the chair will contract to prevent the trunk falling backward, and the only muscle which will be seen to contract is the sartorius. If then the person incline still further back the rectus femoris will be seen to act but without the vasti externus and internus. This, by the way, illustrates the point that one part of an anatomic muscle can take part in a movement and not the rest of it.

The important point is that we have no power to make the rectus contract before the sartorius. The same thing can be shown by flexing the hip when in the position of sitting down, but it is then more difficult to differentiate the muscles, as merely raising the weight of the limb is sufficient to bring out both muscles. Why the sartorius should contract first it is difficult to say, unless it be that, as it arises from the anterior superior iliac spine instead of from the anterior inferior iliac spine, it can exercise more leverage and so is more capable of fine adjustment.

These examples show that in every movement the prime movers contract in a regular orderly sequence and that the muscles successively come into action, adding to their number according to the amount of work that is required to be done.

In describing the mode of action of the prime movers which take part in any movement I raised the question some years ago[1] whether a muscle acting on a rotatory or a ball and socket joint ever takes part as a prime mover in two movements, which are diametrically opposed to each other.

To illustrate this point I will take, first, the action of the supinator longus as a pronator and a supinator of the radio-ulnar articulations; next the action of the upper or clavicular fibers of the pectoralis major, which were stated by Duchenne from electrical stimulation to be both elevators and depressors of the humerus; then the posterior fibers of the deltoid, which were stated by Duchenne also from electric stimulation to be both adductors and abductors of the hanging humerus; and, last, the action of the two sternomastoids in flexing and also extending the head and neck in the position of extreme extension.

As to the first of these examples, the supinator longus, I still consider that it does not take part in both supination and pronation—in fact, I do not think it takes part in either. The opinion which I expressed regarding the clavicular fibers of the pectoralis major as being elevators and never depressors of the humerus I am glad to find has received the approval of Merkel.[2] Next, the posterior fibers of the deltoid I consider to be adductors and never abductors of the humerus—an action about which opinions differ—and, last, the sternomastoids also are, in my opinion, never extensors of the head and neck. The muscle which might act in two opposite ways is the latissimus dorsi, the large flat muscle which extends from the iliac crest and lower half of the spine to the humerus. This muscle has always been described in the text-books as an extraordinary muscle of inspiration, but as I showed ten years ago[3] it is evidently a muscle of expiration, as any one can prove for himself by putting the fingers on the posterior fold of the axilla and giving a good cough, or, if one prefers, indulging in immoderate laughter; and it is evidently one of the muscles which are affected in Milton's line from *L'Allegro:*

Sport that wrinkled care derides
Laughter holding both his sides.

With regard to inspiration, I have found that this muscle does not take part in such severe dyspnea as occurs in pneumothorax or pneumonia, though it does act in the emotional movement of sobbing and yawning. With the exception of the latissimus dorsi, whose action as an inspiratory muscle I think is doubtful, I do not know of any muscle in the body which takes part as a prime mover in two actions diametrically opposed to each other.

SYNERGIC MUSCLES.

Taking next the synergic muscles, of which I have already given one example, I would say that another example is seen in the movement of extending the thumb; here the extensors of the thumb pass over the wrist joint and would abduct this joint, but to prevent this movement, which is not wanted, the ulnar adductors, the flexor carpi ulnaris and the extensor carpi ulnaris contract and thus fix the wrist joint; so that in extending the thumb we contract at the same time the ulnar carpal muscles. Another example is that of the extension of the fingers, where the principal movers are the extensors of the fingers, and the synergic muscles are the flexors of the wrist.

In the movement of supination we have also a good example. The chief supinator is the biceps, but this muscle is also a powerful flexor of the elbow, and yet it is perfectly easy to supinate strongly without flexing the elbow. The explanation is that the biceps takes part in two movements by passing over two joints, viz., flexion of the elbow and supination of the forearm, and if only supination is required the triceps contracts as a synergic muscle and counteracts the flexion of the elbow by the biceps; so that whenever we perform strong supination only, the triceps contracts.

I have recently been examining the action of the synergic muscles in the movements of the leg, which has not, I believe, been previously observed. In flexion of the hip the sartorius acts when the movement is slight and the rectus femoris comes in when the movement becomes stronger. But the sartorius also is a flexor and a rotator in of the knee joint, and the rectus femoris is an extensor of the knee and a more powerful muscle than the sartorius. Therefore, in strong flexion of the hip when the knee is bent, the knee would tend to be extended and also to be rotated in. On carefully examining the muscles at the back of the thigh I find that in this movement the biceps contracts; this muscle, it will be remembered, is the hamstring, which arises by two heads from the femur and from the ischial tuberosity and is inserted into the head of the fibula. The interesting point is that although its tendon becomes tense in this movement, its long head arising from the ischial tuberosity can not be felt to contract. The only actions which are here required of this muscle are flexion and rotation out of the knee, to counteract the extension of the knee by the rectus and the rotation in by the sartorius; the long head does not contract presumably because extension of the hip is not required, as it would be antagonistic to the movement we wish to perform, viz., flexion of the hip.

---

[1] Brain, 1891, p. 51.
[2] Ergebnisse der Anatomie, 1905.
[3] Brit. Med. Jour., Oct. 1, 1898.

Again, extension of the hip is performed by the hamstrings, i. e., the biceps, semimembranosus and semitendinosus, but these muscles also flex the knee, and if the latter movement is not required, as in extending the hanging lower limb against resistance applied to the back of the thigh, the vasti contract to prevent flexion of the knee, but not the rectus femoris, as this last would also tend to flex the hip, a movement which is antagonistic to the one required.

The relation between the prime movers and the synergic muscles is very close, and it seems impossible to contract one without the other. For instance, it is not possible to extend the thumb in the slightest degree without causing a contraction of the extensor and flexor carpi ulnares, and if the prime mover be paralyzed by a lesion of the peripheral nerves the synergic muscles go on contracting and produce movements which are not intended.

As Duchenne pointed out, if the extensors of the fingers be paralyzed or weakened by a peripheral neuritis and the patient be asked to extend the fingers, the only effect is to flex the wrist by the synergic muscles, the flexors of the wrist, which go on contracting as though nothing had happened. The brain sends down a message to the two sets of muscles, and if one set—the prime movers—happens to be weak, the other set—the synergics—get their full amount and produce a movement—flexion of the wrist—which is quite different to extension of the fingers, which was required.

Apparently the brain has no power to moderate the impulse sent to the synergics to make them act proportionately to the weak prime movers. The close relation is also well shown by performing the movement of clenching the fist tightly and at the same time flexing the wrist. In the first movement the flexors of the fingers and thumb contract and also the extensors of the wrist to prevent the wrist being flexed; in the other movement the flexors of the wrist contract strongly. We have, therefore, two different movements to be carried out, and I have found that in the first movement the synergics—the extensors of the wrist—are so closely connected with the prime movers that they will continue acting and will oppose and antagonize the flexors of the wrist, the prime movers in the other movement. This opposition is the cause of the strained effort which is experienced when these two movements are performed at the same time.

The intimate relation is also shown by the fact that the synergic muscles act in all positions of the joint. Duchenne thought that the function of the synergics was to put the muscles of the prime movers in the greatest elongation in order to augument their dynamic power, but this I think can not be their true use, as is shown by the following procedure: If the thumb be extended the synergic muscles, the extensor and flexor carpi ulnares contract to prevent the wrist being abducted; if, however, the wrist be first passively abducted to the radial side, and then the thumb be extended, the synergic muscles will still contract without, however, improving the position of the joint and enabling the extensors of the wrist to work at a greater advantage.

FIXATION MUSCLES.

I have already mentioned the fixation muscles of the flexors of the finger, and I now wish to refer to the extensors of the fingers and their fixation muscles. If the wrist be in the position of pronation, and the fingers be extended against resistance, this resistance if strong enough will tend to overcome the wrist and cause it to flex. So to prevent the wrist from being flexed the extensors of the wrist take part in the movement, and to prevent the elbow being extended by the pressure the biceps contracts. It is to be observed that the extensors of the wrist and the biceps as fixation muscles do not come into action at once, but that a certain amount of resistance has first to be experienced; it seems, however, that as soon as the joints begin to be displaced by the extra pressure then the fixation muscles contract.

In the action of the extensors of the wrist as fixation muscles in the movement of extension of the fingers, an interesting clinical fact has long been observed in lead paralysis. In some cases of lead paralysis we see the following well-known condition: The patient has paralysis of the extensors of the fingers, but not of the extensors of the wrist, and if he be told to extend the wrist in the ordinary way with the fingers flexed he can do so and the tendons of the extensors of the carpus can be felt and be seen to stand out at the wrist. When, however, the patient is told to extend the wrist with the fingers straight, he gets the phalangeal joints straight by means of the interossei and lumbricales muscles which extend those joints, but he is unable to extend the metacarpo-phalangeal joints owing to paralysis of the extensors of the fingers, and the only thing which takes place, as Duchenne pointed out, is that the wrist is flexed owing to the synergic action of the flexors of the wrist, for, as I have already pointed out, whenever we wish to extend the fingers the flexors of the wrist contract to prevent the wrist being extended.

But the most interesting point is that the patient has absolutely no power to make his extensors of the wrist, which are not paralyzed, contract so long as he is trying to extend his wrist with the fingers kept straight, and no tightening of the tendons of the extensors of the wrist can be felt. This condition has been known for some time but had not been explained, and a few years ago I made some observations to see what occur in health. Such observations anyone who wishes can readily make on himself.

Put the left thumb on the back of the right wrist over the tendon of the extensor carpi radialis, and the left first finger over the right flexor carpi ulnaris just above the pisiform bone; let the right fingers remain flexed and extend the wrist, and at once the tendon of the carpi radialis can be felt to contract. If now one starts again and extends the right fingers fully one feels at once the tendon of the synergic muscle, the flexor carpi ulnaris, to contract. If the wrist be now extended, keeping the fingers extended, the flexor carpi ulnaris tendon is still taut, but the thumb does not feel any contraction on the tendon of the extensor carpi radialis, showing that all the work is done by the extensors of the fingers. But if the wrist be now extended, with the fingers extended, against resistance, it can be done by pressing the back of the fingers upward against the under surface of a table, what will happen? After the pressure has reached a certain point the thumb will feel the extensor carpi radialis contracting, which shows that the extensors of the wrist are now assisting the extensors of the fingers to overcome the resistance which would otherwise cause the wrist to flex. The important point is that if the fingers be kept fully extended, the extensors of the wrist will not take part in the movement until the pressure to be overcome is considerable; in my own case it was as much as three or four pounds.

The fact that in health the extensors of the wrist will not take part in the movement of extending the wrist, until there is a fear that the resistance of the wrist will be overcome, places these muscles in the category of fixation muscles, which, as I have already mentioned, do not take part in a movement until there is a certain amount of stress on the joint. In lead paralysis the patient tries to extend his fingers and manages to extend the phalangeal joints by the interossei and lumbricales, but he has no power to contract the paralyzed extensors of the fingers and to produce the tension of three pounds which is necessary to bring into the movement the action of the extensors of the wrist.

The interesting point is that the patient has no power to make the extensors of the wrist contract so long as they are in a secondary position as fixation muscles, but they can do so at once as prime movers.

Another instance of fixation muscles is the contraction of the muscles of the upper arm, which occurs when the fingers and thumb flex in the movement of grasping an object. The flexors of the fingers, arising as they do from the internal condyle of the humerus, have a slight action of flexing the elbow and, especially when the elbow is at a right angle, to prevent this flexion and to steady the elbow joint the triceps contracts, but, like other fixation muscles, it does not contract until a certain amount of displacement takes place. In my own case I can not feel the triceps contract until the dynamometer has registered a grasp of from six to ten pound (3-5 kgs.).

In describing the action of the prime movers I have made mention of the muscles which produce exactly the opposite movement, viz., their antagonists.

For instance, in the movement of flexion of the fingers the antagonists are the extensors of the fingers (but not the extensors of the wrist which are synergic muscles), and in the movement of flexion of the elbow the antagonists are the triceps and anconeus. I do not propose to give you the history of the action of the antagonists and the antagonism which they have given rise to among authors. I would merely say that I think Galen was right and that Winslow and Duchenne were wrong in their ideas of the subject.

Beaunis[4] and Demeny,[5] by means of Marey's myographs, showed that the antagonists relax when any resistance is made to a movement, but that in natural movements (when there is no resistance) and which are at a slow and uniform rate, there occurs a simultaneous action of the antagonists. According to Winslow, who thought that "to move any part . . . all the muscles belonging to it must cooperate," the want of action of the antagonists is in many cases supplied by the weight of the part to which they are fixed or by additional weight. This would mean that when gravity is acting on a limb or a weight is being lifted the antagonists do not act. Therefore, the only time that the antagonists might act is in unopposed movements when gravity is not acting. I have pointed out in a previous communication[6] that the movements of rotation of the head in the erect position are particularly adapted to determine this point, as they are unopposed and not acted on by gravity, and that in rotation of the head by one sternomastoid no contraction can be felt or seen in its antagonist, the other sternomastoid.

In some unopposed movements, which are required to be suddenly stopped, the antagonists certainly do act, but not in opposed movements, as every one experiences when he makes a great effort to lift an empty can which he thinks is full of water, with the result that he lifts it suddenly much higher than was intended.

Professor Sherrington[7] has shown by numerous experiments that electric stimulation of the excitable cerebral cortex not only produces a definite movement by causing contraction of the muscles directly taking part in the movement, but also produces corresponding relaxation of the antagonists by inhibiting their tone, and this occurs with even minimal stimulation.

But perhaps some may say, what does it matter whether the antagonists contract or relax, and does any practical use come from the knowledge? Apart from the dictum that every observation which is correct is worth recording, I do consider that this question of the relaxation of the antagonists is even of practical use to us. It is sometimes very difficult to get a patient to relax certain muscles which we wish to examine, as, for instance, the deltoid muscle—an abductor of the shoulder—when we may wish to know whether the patient is able to abduct the humerus or not, or whether the inability to move the shoulder is due to a rheumatic joint. For this purpose it is only necessary to ask the patient to put the adductor muscles into action, and to strongly adduct the humerus against resistance, when the deltoid will be relaxed. The muscle can then be freely moved between the finger and thumb, and on then telling the patient to abduct his humerus it will be possible to tell at once whether the muscle is capable of contraction or not.

Another use of this knowledge of the relaxation of the antagonists is that in a certain class of cases this relaxation of the antagonists which should normally occur does not do so. About five years ago I described the following condition which occurred in a case of functional paralysis in a girl: She had partial hemiplegia, and when she was told to extend the affected elbow against resistance, in place of the extensor muscles contracting, and the antagonists—biceps, brachialis anticus and supinator longus—relaxing, the antagonists actually contracted first, and the first movement took place in the biceps and supinator longus. This was followed by contraction of the triceps and again by the biceps, giving rise to the to-and-fro hesitating movement which is so characteristic of attempted movements in functional cases.

Since seeing this first case I have come across many cases of functional paralysis showing the same inability to inhibit the antagonists. This condition can also be well seen in the knee; for this purpose the patient lies with the face downward and the leg is put at right angles to the thigh and the patient is directed to extend the knee against resistance. Normally the hamstrings should be relaxed at once, but in these cases these muscles can be seen and felt to contract along with the extensors.

[7] Proc. Roy. Soc., vol. lxxvi, B., 1905.

In the ankle joint the same thing can be seen, by telling the patient to dorso-flex the ankle against resistance. In a normal person the antagonists—the calf muscles—would be relaxed, but in these cases the Achilles tendon can be felt to tighten in place of being relaxed. In all these cases it is necessary for the observer to fix the limb and prevent it moving; otherwise, as the joint is extended or flexed, the antagonists may be passively drawn on and give the impression that their muscles are actively contracting.

What, then, is the significance of this action of the antagonists? The first time that I observed this contraction of the antagonists was seven years ago, in the case to which I have already referred, and which I considered to be hysterical or functional and in which there were no signs of organic disease of the nervous system. It has been considered by some observers, notably by Buzzard, that some of these cases of functional paralysis may be the first stages of disseminated sclerosis, and I have been waiting to see if any of these cases should eventually shows signs of this disease. I have lately had the opportunity of seeing again my first patient, and I find that she does not show after seven years any symptom of sclerosis. There is no nystagmus, no intention tremor, no increase of the deep reflexes and the plantar reflex is of the flexor type.

As I have never seen this condition in disseminated sclerosis or in any other organic disease of the nervous system I consider it to be a symptom of functional disease as opposed to organic. Moreover, I look on this condition as probably the first stage of what is known as hysterical contracture. In hysterical contracture all the muscles—the flexors as well as the extensors—are in a state of tonic contraction, so that the limb is rigid and resists any movement either by flexion or extension. It seems probable that if this intermittent contraction of the prime movers and the antagonists were to become permanent we should have the condition of tonic contraction of all the muscles which goes to produce a general contracture. I have observed that under appropriate treatment, isolation and faradization, this undue action of the antagonists gradually passes off and the muscles return to their natural condition with relaxation of the antagonists when any voluntary movement is performed.

In relation to this condition of the contraction of the antagonists I would call attention to some observations of Sherrington,[8] who, as I stated above, has found that when any particular movement, such as flexion of the elbow, is produced by electrical stimulation of the motor area in the cortex of the monkey, the antagonists are not only relaxed, but their tone is diminished. Recently, however, he has found that under the action of strychnin or of tetanus toxin the antagonists are not relaxed, but, on the contrary, the inhibition which usually takes place is converted into an excitation. We thus have synchronous excitation of antagonistic muscles, and this explains the simultaneous contraction of large inharmonious groups of muscles in strychnin convulsions.

Another point of interest is that in both strychnin and tetanus-toxin poisoning, and as also in functional conditions, the character of the convulsive attacks which are liable to occur is that of overaction of the extensors producing the well-known symptom of opisthotonus and forming in the latter condition the hysterical *arc en cercle* of Charcot and his school. I do not wish to push the analogy too far, but I would merely point out that it is curious that the two conditions in which we obtain the absence of the inhibition of the antagonists and also the presence of convulsive attacks in which the extensors of the spine are strongly involved, are obtained in functional (i. e., hysterical) cases, and also in poisoning by tetanus toxin and strychnin. I suppose that in each case the cause is a loss of control.

According to Sherrington, tetanus and strychnin poisoning "work havoc with the coordinating mechanisms of the central nervous system because in regard to certain great groups of musculature they change the reciprocal inhibitions, normally assured by the central nervous mechanism, into excitations." Sherrington thinks that the reactions elicitable from the cortex cerebri under strychnin are due not to the action of this agent on the cortex but by alterations produced in the spinal and bulbar centers on which the cortex acts. He also states that in other fields of action, as in the arcs of purely sensual and perceptual level, one cortical element may inhibit another cortical element. It seems more probable that in so-called hysterical paralysis the loss of control takes place in the cerebral cortex rather than in the spinal cord and that this loss of control transforms the inhibition of the antagonists into excitation of these muscles.

We have now to sum up the various muscles taking part in a movement and to consider where in the nervous system these muscles are linked together.

We may have, therefore, in any single movement such as the closure of the hand the following classes of muscles taking part: The prime or principal movers, the flexors of the fingers and thumb; the synergic muscles, the extensors of the wrist; and the fixation muscles, the triceps and biceps. The principal movers frequently consist of two or more muscles, and these muscles, as in the case of the flexors of the elbow and of the extensors of the hip, come into action in a definite order according to the amount of work required to be performed, and, further, it seems that the will has no power to alter this order or to make a muscle act out of its turn (except perhaps by trained exercises). Again, in those muscles which have two or more movements by passing over two or more joints, the synergic muscles come into action at the same time as the principal movers, and here again the will has no power to prevent these muscles acting or to leave them out of the list. Lastly we have the fixation muscles, which fix the joint or joints intervening between the joint under examination and the trunk and which do not come into action until a certain pressure and displacement has been brought to bear on the joint.

The question which we have now to consider is in what part of the nervous system are these groups of muscles linked together as to form a movement? There are two places where this may take place—in the spinal cord and in the motor cortex. Now, if we start from the muscles and follow up the motor nerves, where in the nervous system is the first station where such an arrangement of cells exists by which the ultimate component muscles can be combined to form one movement?

It has been shown by the experiments of Sherrington and of May that in the spinal cord coordinated movements can be obtained reflexly in the monkey by stimulating the posterior roots, or the different areas of skin supplied by these roots. According to Sherrington,[7] the inhibition of the antagonists which occurs on stimulation of a peripheral nerve or by excitation of the cortex cerebri, appears in both cases with some likelihood to lie in an internuncial mechanism—synapse or neurone—between the afferent and efferent neurones. He, therefore, thinks with Exner[9] that in the cortical movements the inhibitory phenomena have their chief seat in the spinal mechanisms though elicited from the cortex. Sherrington and Hering also found on stimulating the cut across the internal capsule that the spot where the triceps was inhibited corresponded exactly to the place where the biceps was stimulated to contract.

---

[8] Proc. Roy. Soc., 1905, vol. B., 76.

In favor of the lowest station for cortical movements being in the spinal cord and not in the cortex are the following considerations: There is a mechanism in the cord by which muscles can be coordinated to produce definite movements and by which their antagonists can be inhibited. Coordinated movements with inhibition of the antagonists can be obtained from stimulating the internal capsule similar to those from the cortex cerebri. It is not possible to produce contraction of single muscles by stimulation of the cortex or internal capsule.

Also in a previous communication[10] I have described a case of hemiplegia in which the patient had the power of grasping but had no power to extend the wrist or to extend the elbow in prime movements. When, however, he grasped an object the extensors of the wrist and the extensor of the elbow were put into action, as synergic and fixation muscles, although they could not be made to contract as prime movers. In this case all the muscles taking part in the movement of grasping, even the fixation muscles, were coordinated into action, but these same muscles were paralyzed, when they took part in another movement, where they were prime movers. This showed that these muscles were coordinated at some point below the internal apex.

Further it was found by Ferrier that the coordinated movement of clenching the fist, in which the flexors of the fingers and thumb and the extensors of the wrist took part, could be obtained from stimulation of the motor cortex in the monkey, and Sir Victor Horsley and myself also found the same movement from stimulation of the internal capsule in the monkey.

It hase been considered by some observers—among others by O. Foerster—that this linkage of the ultimate components of a movement takes place in the motor cerebral cortex and that single muscles and not movements are represented in the cortex. This is a doctrine with which I can not agree, as I hold fast to the opinions of John Hunter and Duchenne and particularly of Hughlings Jackson, that "nervous centers know nothing of muscles; they only know of movements."

If the motor cortex were the lowest station, where these muscles are linked together to produce one movement, it would hardly be possible to get the simultaneous action of the flexors of the thumb and fingers together with the synergic action of the extensors of the wrist from stimulation of the internal capsule; and if every combination between different muscles had to be arranged in the cortex and impulses had to be sent from the cortex to each separate muscle the number of fibers required to transmit the various combinations would be much more than is provided for by the internal capsule and the pyramidal tracts.

It seems to me that all the evidence is in favor of the linkage of the ultimate constituents of a movement being in the spinal cord. It has been shown by von Monakow[11] and by Schafer[12] that the pyramidal fibers end in the gray matter at the base of the posterior horns and not in the anterior horns, as was formerly thought, and that probably there exist intermediate cells between the ending of the pyramidal fiber and the anterior cornual cell, and that these have the power to bring about associated movements. A clinical fact which throws light on this subject is mentioned by Foerster[13] as occurring in locomotor ataxia, and it is a condition which I can corroborate. In cases in which there is loss of the sense of position in the upper limbs, if the patient be asked to clench the fist with the eyes open he can do so in a normal manner, but if he tries to do it with the eyes closed the wrist will be flexed at the same time, owing to the want of action of the synergic extensors of the wrist. The reason of this seems to be that the proper combination of the principal movers and of the synergic muscles can not take place if the posterior cornua are affected as they are in some cases of tabes, and the faulty position has to be rectified when the patient has his eyes open by a voluntary extension of the wrist. This, I think, is evidence that the lowest station where these muscles are linked together for a voluntary movement is in the spinal cord. Whether the mechanism by which these voluntary movements are produced is identical with that used for reflex movements is, I think, uncertain.

It therefore seems probable that the mechanism by which the muscles taking part in a single movement are linked together, is situated in the cells of the posterior cornua of the spinal cord, which cells are acted on by impulses from the excitable cerebral cortex. Take, for instance, the action of supination of the foramen. If only a weak action is required as in simply moving the limb, the impulse coming to the posterior cornual cells is weak, and these cells send a message to the anterior cornual cells of the supinator brevis only. If stronger action is required, a stronger impulse is sent to the posterior cornual cells which stimulate the anterior cornual cells of the biceps, and at the same time those of the triceps which act synergically to prevent the elbow from being flexed by the biceps. If a stronger movement still is required the fixation muscles, viz.: the adductors of the shoulder are brought into action by the posterior cornual cells to prevent the humerus being drawn away from the trunk by the very strong pressure to be overcome.

A very good simile is that of an engine room on board an ocean liner. The captain on the bridge sends down messages to the engine room and his orders are put into action by the engineer, but the captain has nothing to do with the mechanism of turning on the particular steam cocks, etc. The captain also gives messages to the man at the wheel, who puts in action the steam steering gear. The captain on the bridge represents the cerebral mechanism, including the motor area, and the engineer represents the posterior cornual cells and turns on the proper amount of steam. The captain does not know what is going on in the engine room, except by his orders being properly carried out, and likewise the brain knows nothing about how the movements are done. If the ship have twin-screws and be driven by turbines, then the engines for going astern will constitute the antagonists to the prime movers for going ahead. The rudder will represent the synergic muscles, and if it be required to turn the ship to the right the rudder will be used to counteract the action of the right screw, which is not required. If the rudder does not act the ship performs a movement, which the captain did not intend, and if the synergic muscle be paralyzed the movement, which the brain ordered, is wrongly carried out, and neither the captain nor the brain knows that it will happen, as the block takes place either in the engine room or at the periphery from the breaking of a screw shaft, i. e., in the anterior horns or in peripheral nerves.

On the other hand, if the mechanism for coordinating the muscles took place entirely in the brain, it would mean that the captain would have to manage all the machinery of the engine room—which would have to be on deck—and would himself have to turn on the necessary steam cocks, and at the same time he would have to steer the ship himself.

135 Harley Street, Cavendish Square, W.

DISCUSSION.

Dr. Charles K. Mills, Philadelphia: Dr. Beevor's illustration of the manner in which movements occur and are coordinated is an appealing one, but at the same time (as in all our efforts to illustrate problems of philosophy or biology) by comparison there may be present some little source of fallacy. The cerebral cortex, I think, at least takes part in the regulation of the manner in which the movements which are coordinated and are arranged for outward expression in the spinal cord occur. Dr. Beevor has by his presentation of the subject of the non-relaxation, or action contrary to intention, of antagonistic muscles in hysterical subjects, given us a valuable addition to our methods of making a diagnosis of hysteria from organic disease.

Dr. F. X. Dercum, Philadelphia: While familiar in a way with Sherrington's results, I was not prepared for the beautiful exposition of muscular movements to which we have just listened. The fact that in a hysterical palsy or hysterical contracture the opponent muscles do not relax is of great practical value—a sign which, like the Babinski sign, will prove useful in differentiating between functional and organic palsies. In regard to the localization of the co-ordinating function, I am inclined to accept Dr. Beevor's view, that the cortex represents the motion only and has nothing to do with the muscles.

What rôle does Dr. Beevor assign to the cerebellum in this beautiful play of action between the cortex and the associations in the spinal cord?

Dr. Hugh T. Patrick, Chicago: There is one muscular sign which Dr. Beevor was the first to observe and describe, that is, the excursion upward of the umbilicus in some cases of paraplegia. Within a week I have had opportunity to observe it in two cases. In one case the sign was not particularly useful because the sensory symptoms made the spinal localization easy; but in the other case there were no sensory symptoms, and the only means of ascertaining the level of the cord where this lesion was, causing complete paraplegia, was what, I believe, Dr. Beevor calls the umbilicus sign. In a severe lesion of the cord at about the tenth dorsal segment, of course the muscles of the abdomen above that level are not paralyzed, and those below that level are. Consequently, with the patient recumbent, if the arms are folded across the chest, and the patient raises the head off the pillow, or perhaps a little better attempts to raise the shoulders, the recti muscles above the umbilicus contract, the recti muscles below can not contract and the umbilicus moves upward one-half an inch, three-fourths of an inch, even an inch. In a case in which the sensory symptoms are not so distinct as to make the level apparent, this sign practically settles the localization. For instance, in a case of spinal tumor with sufficient pressure on the cord to cause paraplegia, with no marked anesthesia, but with imminent danger of destruction of the cord, and with no deformity whatsoever, this Beevor's umbilicus sign tells us just where the tumor is, where the incision should be made, which laminæ are to be removed to expose the tumor.

Dr. Morton Prince, Boston: I recall a number of facts of which Dr. Beevor has not spoken, which are entirely in accord with his main proposition, that is, that this linking together, this association at least, of these movements, is to be found in the spinal cord rather than in the brain. This association, this co-ordination of movements in a certain part of the nervous system, reduced to its simplest terms, is in the final analysis memory.

Since the great classical work of Herring we all know that memory is not simply a conscious attribute, but an attribute of all living matter, of a cell, and the spinal cord as well as of the brain; and therefore, when Dr. Beevor points out that this linking together may be in the spinal cord in such a way as to be reproduced on a certain stimulus from the brain, all he means to say, of course, is that the spinal cord possesses memory, which is well known. The memory of these primary movements and these synergic movements, and of these movements which are a part of all organic matter, is particularly within the function of the spinal cord. Witness the classical experiment of the movements obtained by stimuli applied to a decapitated frog, which is nothing more than the reproduction of these primary and synergic movements; also the experiments of Charington and another on the brainless dog, in which they obtained movements of running, jumping and leaping, all representing these movements which Dr. Beevor has explained, and which, therefore, must be organized and linked together as memories in the spinal cord or in other ganglia. We have a mechanism by which this all can take place in the center below that of the brain; and this fact seems in harmony with the fact that so very few fibers coming down through the foraminal tract can produce this vast variety of movements which we know emanates from below, from the cord. Dr. Beevor's theory of that particular phenomenon which he found in hysteria, namely, the contraction of the antagonistic muscle from lack of inhibition of that antagonistic muscle in hysteria, is entirely in accord with the entire lack of inhibition observed in hysteria.

Dr. William G. Spiller, Philadelphia: I think that in associated movements in another sense, conclusions confirming Dr. Beevor's findings might be drawn. Where, for example, the left upper limb is paralyzed and the man has little control of it, yet there is occasionally seen an associated movement of the right and left upper limbs; as, for example, when the patient closes the right hand, the left closes involuntarily. It is reasonable to believe that associated movements, especially those of a reflex character, at least in part, depend on centers below the cortex, as it is produced even when the right side is cut off from the brain. Goltz's dog ran after the cerebrum was removed. Babinski has stated that it is common in hysteria for the antagonistic muscles to be contracted. Does Dr. Beevor regard that contraction of the antagonistic muscles which he says occurs in hysteria, as the result of suggestion? Babinski holds that all hysterical phenomena are produced by suggestion.

Dr. D. I. Wolfstein, Cincinnati: I once saw Oppenheim differentiate a case of multiple sclerosis from hysteria by the suspected ankle clonus which resulted. The other physicians had considered the movements that they got on the plantar portion of the foot as a distinct dorsal ankle clonus, whereas Oppenheim showed that the movement was upward instead of downward. It would be interesting to know whether that has anything to do with the innervation from the cortex. It seems to me that we must invest the cortex cerebri with an intelligent controlling influence.

In the case of the decapitated frog, when we take a piece of paper and wet it with acid and put it on the back, and see the frog make apparently intelligent motions—just as intelligent probably as if it had a cortex left—what we do see is that there is an excess of somewhat uncontrolled motion resulting in the frog's efforts to liberate itself from the irritation; and it seems to me that the rôle of the cerebrum would be the proper gradation of the exact amount of movement, and the exact amount of force, that is required in stimulating the antagonists and protagonists to produce the proper action.

Dr. H. A. Tomlinson, St. Peter: In my study of the reflexes in newborn babies, I made some observations that tend to confirm the conclusions of Dr. Beevor. In the newborn child the muscles of prehension and locomotion are flexed, and the extremities are flexed and adducted, while the trunk muscles are relaxed. Combinations of reflexes are begun by bringing into play the synergic muscles, then the fixation muscles, and finally the extension or antagonistic muscles. In all coordinate combinations of the reflexes it is fixation and extension that accomplish the movement; so that what I have described as the sequence in the building up of a compound reflex, Dr. Beevor has observed as the sequence in the carrying out of single muscular movements in the adult.

Dr. M. Allen Starr, New York: I consider the matter of differentiation between the organic and the functional type of movement a very valuable point in connection with Dr. Beevor's observation. Possibly his observations have a tendency to confirm a position advanced in 1904 by Lapinsky in the *Deutsche Zeitschrift für Nervenheilkunde.* We have always been taught that each group of cells in the cord is related to a muscle, and that when that muscle moves that one group of cells is called into play. Lapinsky took the position that each group of cells in the spinal cord is not related to a muscle, but to a movement; and that therefore, when I flex my fist I do so by sending a cortical impulse down through the pyramidal tract to a group of cells, which group of cells is thrown into activity and innervates the various muscles; and he substantiated this position by citing the well-known fact that a single group of cells sends out its motor neurons to the anterior motor nerve roots; those motor nerve roots split up in the various plexuses; consequently a given group of cells of the spinal cord sends out impulses to a great number of different muscles. I have seen no reference to this interesting theory, opposed, as you see, to all our doctrines of the relations of spinal functions, and the relations of groups of cells to groups of muscles; but it seems to me important in connection with these observations of Dr. Beevor, for it supplies us immediately with the spinal mechanism which will explain the action of these various muscles without forming a connection between the pyramidal tract and the group of cells in the cord—a hypothetical group of cells in the posterior horns of the cord which he brings in—hypothetical, because we do not know of groups of cells in that portion of the tract. Therefore, this theory of Lapinsky would substantiate in that way Dr. Beevor's conclusion, giving us a physico-anatomic basis for the findings that Dr. Beevor has made from the physiologic side.

Dr. Charles K. Mills, Philadelphia: Taking Dr. Beevor's illustration of the captain and the engineer and the machinery; has not a given region of the cerebral cortex the power, so to speak, to elect that a simple movement, a movement less simple, a complicated and a more and more complicated movement, shall be performed by the machinery, whatever it is, in the lower levels of the nervous system; and if this be the case in the sense in which we ordinarily use our words in describing cerebral localization, do not given regions of the cerebral cortex even represent the prime and synergic and antagonistic and all of these coordinated movements? That seems to me the crucial question in this discussion.

Dr. Julius Grinker, Chicago: Has Dr. Beevor included in his beautiful experiments the involuntary contractions of single muscles and the disorders of associated movements which are regular phenomena of Sydenham's chorea? Most writers on chorea place the disease either in the cerebellar cortex or in the cerebrum. Otto Foerster, who has made an extensive study of the motor phenomena of chorea, places the disorder in the cerebellum. He says that whenever a movement is conceived in the cortex, two impulses are sent out, one through the pyramidal tract (this neuron arborizes around the anterior horn of the cell) and another impulse is sent by way of the cerebellum, to which organ he assigns the rôle of coordinating the movement conceived in the motor cortex. Both movements reach the same cell, one from the cortex of the cerebral motor area, the other somewhere from the frontal lobe by way of the cerebellum and into the anterolateral region, eventually arborizing around the motor cell. He explains chorea as a disorder of the cerebellum which frustrates the plans of the voluntary impulse by either producing a useless movement, namely, contracting the antagonists rather than the so-called agonists or the synergists; the result being just exactly the opposite of what was intended; or, he thinks possibly, the impulse is side-tracked and some other muscles than those intended, contract. Of course he is unable to substantiate the opinion by pathologic proof.

Dr. Archibald Church, Chicago: I believe that the so-called spurious foot clonus of hysteria may bear on the conclusions in Dr. Beevor's paper. In such cases there is always a contraction of muscles on the front of the leg when developing the clonus. In organic clonus, as from a spinal or cerebral lesion, I have failed to see the participation of the muscles on the front of the leg; and Dr. Beevor's exposition seems to substantiate my observation as to the participation of antagonists in this particular hysterical condition. I have noticed that the primary attempt of children in grasping an object is one of extension of the wrist, and I have thought this a reversionary element, that extension must precede prehension, but Dr. Beevor's wonderfully lucid and clear exposition would indicate another application of this idea of the orderly arrangement of muscular action in the simplest movement.

Dr. Albert E. Sterne, Indianapolis: We have always been, I believe rightly, accustomed to consider the cerebral cortical centers as those which originate impulses. The centers lower down in the spinal axis are in their functions probably wholly inhibitive and guiding. We must not forget that in the scale of evolution the centers high up are those which gain in dignity, and that the centers which we commonly look on as being the lower centers are those which in the lower type of animals come into greater prominence. It seems to me that it is but natural in the process of evolution that much of the function which is present in lower animals (practically an automatic function) should exist to a very great degree in human beings. I believe that the theory and the application of the theory which Dr. Beevor has placed before us may well embrace the mass of known facts that we have before us, and I feel as nearly sure as possible, that most known phenomena will fit in with the ideas presented in Dr. Beevor's most interesting and remarkable paper.

Dr. Charles E. Beevor: I do not want to bring in the subject of cerebral movements, but to consider exclusively one single movement; therefore, I have not taken up the consideration of the combination or coordination of several movements, such for instance, as we find in the act of walking. Considering one movement only, the question is where the muscles are joined together and combined to form this movement, whether it is in the spinal cord, or whether it is in the cortex. I always considered it in the spinal cord until I read that matter up and found that some people thought it might be in the brain. If it is in the brain or cortex you ought to get a single movement of the single muscle by itself, that is a movement of the biceps without the movement of any other muscle; but I have never seen that occur.

Then the question is with reference to a single movement. Messages are sent down from the cortex. I agree with Dr. Mills that the cortex has the power of combining movements; but it seems to me that in a single movement like extension of the thumb, the muscles are all combined together in the spinal cord, and especially in the posterior horns, and that a message sent down is not sent to every individual muscle, but to a set of the cells of the posterior horn, which has the power of bringing in muscles one after another, according to the amount of stimulation sent down; but any combination of movements would necessarily take place in the cortex to start with. It would otherwise be necessary to send down a vast multitude of fibers; you would want to send down a fiber to the flexors of the finger, and another to the extensors to the wrist and to the fixation muscles; if you consider the various combinations, a pyramidal tract and internal capsule of immense size would really be necessary. The captain sends down one message, "Go ahead;" he does not tell the engineer how much steam power to use, nor does he attend to any of the details; and all the details are attended to in the engine-room and elsewhere.

Of course I have not taken the cerebellum into account, because I have only taken a single muscle and not a combination. The cerebellum is the center where movements of balance take place, but you can not balance with only one muscle.

I do not know anything about the corpus striatum. As to whether it is excitable or not, people differ. In some work I did with Victor Horsley some years ago, we stimulated the corpus striatum with negative results. We found that if we got near to the internal capsule we got movements, and the movements were precisely the same as we got from the internal capsule only less in degree, and weaker and weaker the further from the internal capsule we got.

Therefore we concluded that there is no evidence that the corpus is excitable, and the result was really due to the stimulation of the internal capsule. Dr. Prince and I agree that it may be a question of memory. I agree also that want of inhibition is the great point in hysteria.

At a meeting in Berne I saw a dog without any cerebrum running about, but that can not occur with a monkey. Goltz used a dog and Fourier used a monkey, and of course they could not agree. I think the monkey is nearer to man than he is to the dog. I think that want of control not suggestion is concerned with hysteria. The movements of the frog trying to rub off an irritating substance is a matter of the coordination of several muscles—a matter which I have not been considering.

I studied a number of newborn children to see whether in the youngest child coordination took place—that is, whether when the child grasps, the hand goes round or not, and I think in about half the cases the arm muscle went around, and in the other half it did not. Dr. Robinson showed years ago that you can hang up a newborn child by the hands and it will hold on to a rail.

I once thought that coordination of muscular movement takes place in the anterior horns, but I have come to the conclusion that probably it takes place in the posterior horns.

In regard to chorea I have not induced the antagonist to act in the same way. But there again it is a question of combined movements and not one single movement. No doubt the patient performs the wrong movement, but it is a wrong movement as a rule, and not an antagonistic movement.

I have observed that the muscles in front of the leg contract in ankle clonus, as Dr. Church observes.

Serum Sickness from Antitoxin Treatment of Tetanus.—Savariaud reports in the *Tribune Médicale*, June 13, the case of a girl of 8 who scraped her knee in falling on the gravel and three days later began to limp and was brought to him. Besides rest and simple local measures he advised an injection of antitetanus serum, assuring the family that it was absolutely harmless. Five days after a second injection, at the tenth day, severe pains developed in the joints and the child could scarcely move her neck and limbs, while especially on the forearms and in the inguinal and axillary regions erythematous patches suggested an eruptive disease. The eruption subsided in fifteen hours, but fever persisted for six days and the pains in the joints for four or five. He cites a few cases of similar disturbances from serum treatment, observed in France, remarking that these accidents are neither frequent nor serious, but that their possibility must be borne in mind.

INSANITIES CAUSED BY ACUTE AND CHRONIC INTOXICATIONS WITH OPIUM AND COCAIN.

A STUDY OF 171 CASES. SUGGESTIONS FOR LEGISLATIVE AND OTHER MEASURES. THE QUESTION OF RESPONSIBILITY.*

ALFRED GORDON, M.D.
Associate in Nervous and Mental Diseases, Jefferson Medical College;
Neurologist to Mount Sinai Hospital, Douglass Memorial
Hospital and Northwestern General Hospital.
PHILADELPHIA.

During the last seven years I have been collecting cases of intoxication with morphin and cocain. The majority are cases observed in hospitals. Confining myself to the effect of the drugs on the cerebral functions, and especially on the mentality, I am able to divide the 171 cases into two groups, viz.: 80 of acute and 91 of chronic poisoning. The first group comprises 60 cases of morphin, 15 of cocain and 5 of mixed intoxication. The second group is composed of 70 morphin habitués, 10 cocain habitués and 11 patients with mixed intoxication.

The permanent effect of the poison did not depend altogether on the mode of its administration or amount absorbed. For a normal adult 6 or 7 cgm. hypodermically constitute a toxic dose, but individual susceptibility should be taken into consideration. Cases of recovery have been reported even with doses of 75 cgm. of morphin.

Habit is very rapidly established.

FIRST GROUP.—A. ACUTE INTOXICATION WITH OPIUM OR MORPHIN (SIXTY CASES).

In this category are placed patients who showed signs of intoxication even after one dose of the drug. When the dose is not immediately fatal, there is at first some agitation without delirium. The patient is loquacious. The mental faculties are stimulated. There is a feeling of beatitude, of euphoria. Soon heaviness of the head and vertigo make their appearance. The latter is followed by somnolence. The general sensations and special sensorium become obtunded, the patient enters into a profound sleep during which death may ensue. In grave cases the respiration is slow, viz., five or six respiratory movements a minute. The pulse is small, irregular; the face is congested, the temperature is lowered. Urine decreases in quantity. Convulsions occur during the last period. In five cases somnolence was absent and the agitation of the first period persisted and was accompanied by a delirium with terrifying hallucinations of sight and hearing.

In seven cases the terminal coma gradually disappeared. The patients regained consciousness and apparently recovered, when at the end of 12, 24 and 36 hours a new attack of coma supervened with rapid death. It is probable that a new absorption of the poison occurred which during a number of hours remained inactive in some portion of the digestive tract.

Recovery may follow even after long hours of coma. During convalescence are observed vertigo, mental hebetude, temporary aphasia or blindness, and many intelligent probably as if it had a cortex left—what we do see is that there is an excess of somewhat uncontrolled motion resulting in the frog's efforts to liberate itself from the irritation; and it seems to me that the rôle of the cerebrum would be the proper gradation of the exact amount of movement, and the exact amount of force, that is required in stimulating the antagonists and protagonists to produce the proper action.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Dr. H. A. Tomlinson, St. Peter: In my study of the reflexes in newborn babies, I made some observations that tend to confirm the conclusions of Dr. Beevor. In the newborn child the muscles of prehension and locomotion are flexed, and the extremities are flexed and adducted, while the trunk muscles are relaxed. Combinations of reflexes are begun by bringing into play the synergic muscles, then the fixation muscles, and finally the extension or antagonistic muscles. In all coordinate combinations of the reflexes it is fixation and extension that accomplish the movement; so that what I have described as the sequence in the building up of a compound reflex, Dr. Beevor has observed as the sequence in the carrying out of single muscular movements in the adult.

Dr. M. Allen Starr, New York: I consider the matter of differentiation between the organic and the functional type of movement a very valuable point in connection with Dr. Beevor's observation. Possibly his observations have a tendency to confirm a position advanced in 1901 by Lapinsky in the *Deutsche Zeitschrift für Nervenheilkunde*. We have always been taught that each group of cells in the cord is related to a muscle, and that when that muscle moves that one group of cells is called into play. Lapinsky took the position that each group of cells in the spinal cord is not related to a muscle, but to a movement; and that therefore, when I flex my fist I do so by sending a cortical impulse down through the pyramidal tract to a group of cells, which group of cells is thrown into activity and innervates the various muscles; and he substantiated this position by citing the well-known fact that a single group of cells sends out its motor neurons to the anterior motor nerve roots; those motor nerve roots split up in the various plexuses, consequently a given group of cells of the spinal cord sends out impulses to a great number of different muscles. I have seen no reference to this interesting theory, opposed, as you see, to all our doctrines of the relations of spinal functions, and the relations of groups of cells to groups of muscles; but it seems to me important in connection with these observations of Dr. Beevor, for it supplies us immediately with the spinal mechanism which will explain the action of these various muscles without forming a connection between the pyramidal tract and the group of cells in the cord—a hypothetical group of cells in the posterior horns of the cord which he brings in—hypothetical, because we do not know of groups of cells in that portion of the tract. Therefore, this theory of Lapinsky would substantiate in that way Dr. Beevor's conclusion, giving us a physico-anatomic basis for the findings that Dr. Beevor has made from the physiologic side.

Dr. Charles K. Mills, Philadelphia: Taking Dr. Beevor's illustration of the captain and the engineer and the machinery; has not a given region of the cerebral cortex the power, so to speak, to elect that a simple movement, a movement less simple, a complicated and a more and more complicated movement, shall be performed by the machinery, whatever it is, in the lower levels of the nervous system; and if this be the case in the sense in which we ordinarily use our words in describing cerebral localization, do not given regions of the cerebral cortex even represent the prime and synergic and antagonistic and all of these coordinated movements? That seems to me the crucial question in this discussion.

Dr. Julius Grinker, Chicago: Has Dr. Beevor included in his beautiful experiments the involuntary contractions of single muscles and the disorders of associated movements which are regular phenomena of Sydenham's chorea? Most writers on chorea place the disease either in the cerebellar cortex or in the cerebrum. Otto Foerster, who has made an extensive study of the motor phenomena of chorea, places the disorder in the cerebellum. He says that whenever a movement is conceived in the cortex, two impulses are sent out, one through the pyramidal tract (this neuron arborizes around the anterior horn of the cell) and another impulse is sent by way of the cerebellum, to which organ he assigns the rôle of coordinating the movement conceived in the motor cortex. Both movements reach the same cell, one from the cortex of the cerebral motor area, the other somewhere from the frontal lobe by way of the cerebellum and into the anterolateral region, eventually arborizing around the motor cell. He explains chorea as a disorder of the cerebellum which frustrates the plans of the voluntary impulse by either producing a useless movement, namely, contracting the antagonists rather than the so-called agonists or the synergists; the result being just exactly the opposite of what was intended; or, he thinks possibly, the impulse is side-tracked and some other muscles than those intended, contract. Of course he is unable to substantiate the opinion by pathologic proof.

Dr. Archibald Church, Chicago: I believe that the so-called spurious foot clonus of hysteria may bear on the conclusions in Dr. Beevor's paper. In such cases there is always a contraction of muscles on the front of the leg when developing the clonus. In organic clonus, as from a spinal or cerebral lesion, I have failed to see the participation of the muscles on the front of the leg; and Dr. Beevor's exposition seems to substantiate my observation as to the participation of antagonists in this particular hysterical condition. I have noticed that the primary attempt of children in grasping an object is one of extension of the wrist, and I have thought this a reversionary element, that extension must precede prehension, but Dr. Beevor's wonderfully lucid and clear exposition would indicate another application of this idea of the orderly arrangement of muscular action in the simplest movement.

Dr. Albert E. Sterne, Indianapolis: We have always been, I believe rightly, accustomed to consider the cerebral cortical centers as those which originate impulses. The centers lower down in the spinal axis are in their functions probably wholly inhibitive and guiding. We must not forget that in the scale of evolution the centers high up are those which gain in dignity, and that the centers which we commonly look on as being the lower centers are those which in the lower type of animals come into greater prominence. It seems to me that it is but natural in the process of evolution that much of the function which is present in lower animals (practically an automatic function) should exist to a very great degree in human beings. I believe that the theory and the application of the theory which Dr. Beevor has placed before us may well embrace the mass of known facts that we have before us, and I feel as nearly sure as possible, that most known phenomena will fit in with the ideas presented in Dr. Beevor's most interesting and remarkable paper.

Dr. Charles E. Beevor: I do not want to bring in the subject of cerebral movements, but to consider exclusively one single movement; therefore, I have not taken up the consideration of the combination or coordination of several movements, such for instance, as we find in the act of walking. Considering one movement only, the question is where the muscles are joined together and combined to form this movement, whether it is in the spinal cord, or whether it is in the cortex. I always considered it in the spinal cord until I read that matter up and found that some people thought it might be in the brain. If it is in the brain or cortex you ought to get a single movement of the single muscle by itself, that is a movement of the biceps without the movement of any other muscle; but I have never seen that occur.

Then the question is with reference to a single movement. Messages are sent down from the cortex. I agree with Dr. Mills that the cortex has the power of combining movements; but it seems to me that in a single movement like extension of the thumb, the muscles are all combined together in the spinal cord, and especially in the posterior horns, and that a message sent down is not sent to every individual muscle, but to a set of the cells of the posterior horn, which has the power of bringing in muscles one after another, according to the amount of stimulation sent down; but any combination of movements would necessarily take place in the cortex to start with. It would otherwise be necessary to send down a vast multitude of fibers; you would want to send down a fiber to the flexors of the finger, and another to the extensors to the wrist and to the fixation muscles; if you consider the various combinations, a pyramidal tract and internal capsule of immense size would really be necessary. The captain sends down one message, "Go ahead;" he does not tell the engineer how much steam power to use, nor does he attend to any of the details; and all the details are attended to in the engine-room and elsewhere.

Of course I have not taken the cerebellum into account, because I have only taken a single muscle and not a combination. The cerebellum is the center where movements of balance take place, but you can not balance with only one muscle.

I do not know anything about the corpus striatum. As to whether it is excitable or not, people differ. In some work I did with Victor Horsley some years ago, we stimulated the corpus striatum with negative results. We found that if we got near to the internal capsule we got movements, and the movements were precisely the same as we got from the internal capsule only less in degree, and weaker and weaker the further from the internal capsule we got.

Therefore we concluded that there is no evidence that the corpus is excitable, and the result was really due to the stimulation of the internal capsule. Dr. Prince and I agree that it may be a question of memory. I agree also that want of inhibition is the great point in hysteria.

At a meeting in Berne I saw a dog without any cerebrum running about, but that can not occur with a monkey. Goltz used a dog and Fourier used a monkey, and of course they could not agree. I think the monkey is nearer to man than he is to the dog. I think that want of control not suggestion is concerned with hysteria. The movements of the frog trying to rub off an irritating substance is a matter of the coordination of several muscles—a matter which I have not been considering.

I studied a number of newborn children to see whether in the youngest child coordination took place—that is, whether when the child grasps, the hand goes round or not, and I think in about half the cases the arm muscle went around, and in the other half it did not. Dr. Robinson showed years ago that you can hang up a newborn child by the hands and it will hold on to a rail.

I once thought that coordination of muscular movement takes place in the anterior horns, but I have come to the conclusion that probably it takes place in the posterior horns.

In regard to chorea I have not induced the antagonist to act in the same way. But there again it is a question of combined movements and not one single movement. No doubt the patient performs the wrong movement, but it is a wrong movement as a rule, and not an antagonistic movement.

I have observed that the muscles in front of the leg contract in ankle clonus, as Dr. Church observes.

Serum Sickness from Antitoxin Treatment of Tetanus.—Savariaud reports in the *Tribune Médicale*, June 13, the case of a girl of 8 who scraped her knee in falling on the gravel and three days later began to limp and was brought to him. Besides rest and simple local measures he advised an injection of antitetanus serum, assuring the family that it was absolutely harmless. Five days after a second injection, at the tenth day, severe pains developed in the joints and the child could scarcely move her neck and limbs, while especially on the forearms and in the inguinal and axillary regions erythematous patches suggested an eruptive disease. The eruption subsided in fifteen hours, but fever persisted for six days and the pains in the joints for four or five. He cites a few cases of similar disturbances from serum treatment, observed in France, remarking that these accidents are neither frequent nor serious, but that their possibility must be borne in mind.

INSANITIES CAUSED BY ACUTE AND CHRONIC INTOXICATIONS WITH OPIUM AND COCAIN.

A STUDY OF 171 CASES. SUGGESTIONS FOR LEGISLATIVE AND OTHER MEASURES. THE QUESTION OF RESPONSIBILITY.*

ALFRED GORDON, M.D.
Associate in Nervous and Mental Diseases, Jefferson Medical College; Neurologist to Mount Sinai Hospital, Douglass Memorial Hospital and Northwestern General Hospital.
PHILADELPHIA.

During the last seven years I have been collecting cases of intoxication with morphin and cocain. The majority are cases observed in hospitals. Confining myself to the effect of the drugs on the cerebral functions, and especially on the mentality, I am able to divide the 171 cases into two groups, viz.: 80 of acute and 91 of chronic poisoning. The first group comprises 60 cases of morphin, 15 of cocain and 5 of mixed intoxication. The second group is composed of 70 morphin habitués, 10 cocain habitués and 11 patients with mixed intoxication.

The permanent effect of the poison did not depend altogether on the mode of its administration or amount absorbed. For a normal adult 6 or 7 cgm. hypodermically constitute a toxic dose, but individual susceptibility should be taken into consideration. Cases of recovery have been reported even with doses of 75 cgm. of morphin.

Habit is very rapidly established.

FIRST GROUP.—A. ACUTE INTOXICATION WITH OPIUM OR MORPHIN (SIXTY CASES).

In this category are placed patients who showed signs of intoxication even after one dose of the drug. When the dose is not immediately fatal, there is at first some agitation without delirium. The patient is loquacious. The mental faculties are stimulated. There is a feeling of beatitude, of euphoria. Soon heaviness of the head and vertigo make their appearance. The latter is followed by somnolence. The general sensations and special sensorium become obtunded, the patient enters into a profound sleep during which death may ensue. In grave cases the respiration is slow, viz., five or six respiratory movements a minute. The pulse is small, irregular; the face is congested, the temperature is lowered. Urine decreases in quantity. Convulsions occur during the last period. In five cases somnolence was absent and the agitation of the first period persisted and was accompanied by a delirium with terrifying hallucinations of sight and hearing.

In seven cases the terminal coma gradually disappeared. The patients regained consciousness and apparently recovered, when at the end of 12, 24 and 36 hours a new attack of coma supervened with rapid death. It is probable that a new absorption of the poison occurred which during a number of hours remained inactive in some portion of the digestive tract.

Recovery may follow even after long hours of coma. During convalescence are observed vertigo, mental hebetude, temporary aphasia or blindness, and many other physical manifestations, including such as constipation, vomiting, retention of urine, albuminuria and myosis.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908

Fifty-two patients in my series of acute intoxication recovered. Thirty-five presented for weeks mental disturbances deserving special attention. They showed slowness of thought and difficulty of grasping complicated subjects. Questions had to be repeated a number of times before they could comprehend them. There was striking mental fatigue. All these patients were particularly annoyed by dreams, which in the majority of cases were of a pleasant nature.

These thirty-five patients used about the same amount of opium or morphin as the seventeen who did not present prolonged mental disturbances. Some of them had only one dose, others two or three doses, and still others a daily dose for a week. There was no direct relation between the amount taken and the symptoms. For example, some of the thirty-five patients who presented prolonged mental disturbances used a smaller amount of morphin than those who recovered promptly. The question is, therefore, one of individual susceptibility. Nevertheless, it is well to remember that even one large dose is likely to disturb the mental functions for a period of several weeks.

FIRST GROUP.—B. ACUTE COCAIN INTOXICATION (FIFTEEN CASES).

As soon as cocain enters the general circulation it acts on the brain and spinal cord.

Precordial pain, rapid and filiform pulse, lividity of the face, cold extremities, cold perspiration, Cheyne-Stokes respiration and anuria are the immediate symptoms. The mental manifestations in nine of my cases were mainly excitation, restlessness, loquacity, crying or anger.

In six cases there was a state of depression and a semistuporous condition, accompanied by nausea, tachycardia, mydriasis and abundant perspiration. In all there was a certain degree of vertigo with ataxia in gait and peculiar hallucinations. The latter were visual and tactile. The visual consisted of black insects and rats. The tactile hallucinations were a tingling, pinching and the sense of holding imaginable objects in the hands.

Four of my patients had generalized convulsive seizures without a previous history of epilepsy. The seizures were followed by a semicomatose state, lasting from one to three days.

Nine patients recovered completely. Two died at the end of twenty-four hours and four days, respectively. The first swallowed, with suicidal intent, eight grains of cocain. His cerebral symptoms were stupor and hallucinations. He died in syncope. The other patient, also suicidal, lived four days with [illegible] of extreme agitation, delirium and [illegible]. He died from exhaustion.

The four patients who presented epileptiform attacks, although they eventually recovered, nevertheless for six subsequent weeks suffered from insomnia, anorexia, diarrhea, vertigo and attacks of delirium. One was unable to resume his occupation of office clerk for six months; his memory was deficient and he could not solve the simplest mathematical problems without making mistakes. His intoxication followed two injections of cocain into the gum for some alveolar operation. The dose could not be determined.

FIRST GROUP.—C. ACUTE MIXED INTOXICATION (FIVE CASES).

The intoxication followed external application of cocain (snuff) and internal administration of laudanum (two cases), also a hypodermic injection of morphin (one case) (for relief of an attack of tic douloureux), together with an external application of 10 per cent. cocain to the cheek, which had erosions. Two medical students, suffering from a severe coryza, used a 15 per cent. cocain solution as a spray and ½ grain of morphin internally.

The most prominent symptoms in all five cases was a very marked stuporous state with paroxysms of delirium and visual hallucinations. The tactile hallucinations characteristic of cocain intoxication were absent. Myosis, constipation, anuria, coldness of the extremities and difficult respiration were also present.

When the acute symptoms disappeared, a mental dulness, apathy, remained for two weeks in one case and for seven weeks in four cases. Eventually all the patients recovered.

SECOND GROUP.—A. CHRONIC INTOXICATION WITH MORPHIN AND OPIUM (SEVENTY CASES).

In considering the manifestations of morphinism I made a comparative study of cases of months' and years' duration.

Twenty cases ranged between two and eight months, and fifty cases between two and twenty-two years of chronic intoxication.

The majority of the patients used morphin; some, however, took opium. Among the latter I had eleven men, of whom six took internally and five smoked opium, with five women who smoked opium and six women who drank laudanum daily.

Morphin was used mostly hypodermically, but in some cases also by the mouth. The amount varied from eight grains to fifty grains of morphin, internally or hypodermically, or from three to twelve drams of laudanum. The amount of smoked opium could not be determined.

The effect of morphinism is somewhat different from abstention from morphin or opium. I had the opportunity to study twenty-six cases during the period of abstention. Speaking generally, the ultimate effect of chronic abuse of opium and morphin is practically the same.

The twenty cases in which the intoxication lasted only months and the fifty cases in which the intoxication lasted years presented but slight differences. In the main, the symptoms were identical.

Description.—With each new administration of opium or morphin there is at first a muscular weakness, languor, an imperative necessity for rest; the pulse is diminished in frequency, and the respiration becomes somewhat difficult. Soon, however, the condition changes. A cerebral excitation takes place, the intellectual functions become exalted. In the intervals between individual doses, such patients exhibit the following important symptoms: Intelligence is lowered. Memory is decidedly impaired. The mental energy is weakened. The aptitude for work is lessened. There is a sort of apathy in the patient's thoughts and acts. The moral sense suffers profoundly. The patient loses the sense of obligation to his family, he loses affection for his children, becomes egotistic. His will power is decidedly deficient. One of the patients, a married woman, frequented a disreputable house, not for sexual reasons, but for the purpose of procuring money for morphin. Another woman became a kleptomaniac for the same reason. Not infrequently these individuals commit excesses of all sorts and even crimes. Deception and lies are common. These general symptoms were present in ten cases. In the remaining sixty there were special mental manifestations characteristic of certain psychoses.

Melancholia: The morbid phenomena of melancholia were observed in eight cases. Here the depression with a tendency to suicide was very marked. However, there were also incoherence, some confusion and a mild degree of dementia. The latter symptoms are not characteristic of typical melancholia. It is true that they are found in the period of terminal dementia, but then the suicidal tendency is usually absent.

Mania: Maniacal agitation with apparent lucidity, alternating with periods of depression, was observed in nine cases. Again the condition simulated the manic depressive form of insanity, but the evolution of the symptoms was not characteristic of it.

Delusions: Systematized delusions of a persecutory nature were noticed in only five cases.

Unclassifiable Symptoms: The remaining thirty-eight cases presented symptoms of an unclassifiable nature. Some of them would reveal delusions of an unsystematized nature, fragmentary, fleeting, changing from day to day, from one examination to another. They were mostly of a persecutory type; some of them presented the expansive form. Delusions of erotic nature figured in many cases. Hypochondriacal delusive ideas were absent. Hallucinations were auditory or visual, more of the latter than of the former. Incoherence and confusion were present in all the cases.

Dementia: This was the prominent feature, especially in cases that were free from delusions and hallucinations. There was a childishness in actions and words and demeanor. The general attitude and appearance were those of dementia due to other causes. To illustrate, the patient smiles and laughs without cause or on the least provocation. When spoken to, he looks up astonished; if an answer follows, it has either no relation to the questions asked or it will be considerably delayed. In some cases the patients are extremely talkative and one question is sufficient to start a conversation which does not cease unless you interrupt it. Two patients of my series in very advanced periods of their morphinism (10 and 14 years of continuous use) could talk at least for a half an hour without pausing. The sentences they used had no connection with one another. The dementia in the majority of my cases was mild, especially in those with the unsystematized delusions and hallucinations, but was marked in cases in which the latter were absent.

Physical Signs: The psychic disorder is usually accompanied by physical signs of chronic poisoning, viz.: muscular asthenia, tremor, anesthesia or hyperesthesia, obstinate constipation, impotence, disturbance of micturition, diminution of salivary, sebaceous, gastric, menstrual and spermatic secretions but increase of perspiration, loss of reflexes and, finally, an especial facies. The last appears to be old and wrinkled.

SECOND GROUP.—B. CHRONIC INTOXICATION WITH COCAIN (TEN CASES).

In six of these cases the habit was acquired while under treatment for nasal affections. They used the drug for from three to eight years. Four patients used cocain for a period of from six to ten years. They acquired the pernicious habit by being advised to use at first the snuff and later internally to get relief from migraine and gastralgia.

Psychic Disturbances.—Besides the physical signs, such as tachycardia, pallor of the face and impotence, the patients presented interesting psychic disturbances. Insomnia was a constant symptom in my cases. In such patients there is restlessness and craving for muscular and intellectual activity. The hallucinations seen in acute poisoning are still more marked in the chronic form. They affect the general sensibility, also sight, hearing and touch. The patient feels that the skin is filled with insects, microbes, crystals of cocain. Sometimes he feels electric shocks, cramps or shooting pains. He sees animals, human beings, shadows, colors, change in the size of objects. He hears voices, sounds, noises. When the muscular sense is altered, the patient feels that he is lifted up in space, carried and abandoned. The hallucinations lead to the formation of delusive ideas which are mostly of a persecutory nature. Systematization of these ideas is very rare (one case); they are mostly unsystematized and vague. Alongside of hallucinations and delusions, there is a gradual and progressive decrease of intellectual force and moral sense. The patient becomes indifferent. His instinct predominates. He is filthy. Dementia is the final outcome.

SECOND GROUP.—C. CHRONIC MIXED INTOXICATION (ELEVEN CASES).

All my eleven cases acquired the habit at first in attempts of substituting cocain for morphin and later by using both drugs simultaneously. Morphin was used hypodermically and cocain by the mouth.

The special hallucinatory images mentioned above in connection with cocainism are all present here, in addition to insomnia and delusive ideas, but what characterizes the mixed intoxications is the more rapid development of the intellectual and moral reduction. The dementia appears early when compared with the date of its appearance in isolated intoxications. In one of the eleven cases the patient, a young physician, presented during a period of four years a systematized persecutory delusion concerning his mother and two brothers who conspired against him. Later he included another physician and myself in his delusive idea. The latter was intensified by terrifying hallucinations. He attempted to kill his mother on two occasions. The previous history of the patient did not warrant the diagnosis of paranoia. However, the paranoid delusion rendered him dangerous. He had to be confined in an asylum. There he was entirely deprived of cocain and morphin and he gradually recovered. Six months later he resumed his old habit and again the same persecutory delusion made its appearance. Again he was committed. A sojourn of four months in an asylum removed all the symptoms. At present he is showing evidences of mild dementia, although there is no return to the drugs.

MORBID MANIFESTATIONS OF ABSTENTION.

Several (26) of the morphin and a few (5) of the cocain habitués were kept under observation, while the drugs were entirely and suddenly withdrawn. The following symptoms could be noticed: Both categories of patients presented a picture of extreme suffering; they were restless, full of anxiety, agitated and incapable of listening to others, following a conversation, of reasoning or of reflecting. Delirium and hallucinations were present in some cases, especially in those of mixed intoxication. Some patients would be taken suddenly with chills, accompanied by twitchings. Others showed a tendency to faint. Insomnia was common and persistent. A few of the morphin habitués had morbid impulses. They would suddenly jump out of bed and attack their nurses and relatives or throw objects at them. The cocain habitués continued having the tactile hallucinations, but to a lesser degree than when the drug was used.

The delusional ideas diminished in intensity, but those who presented signs of dementia did not show any improvement in the mental condition. Besides, the physical condition in the majority of the patients became so alarming that occasionally a return to the drugs was absolutely necessary.

In cases of gradual withdrawal there are symptoms of general malaise, of anxiety, of depression. Photophobia and hyperacusis are present; loss of appetite, diarrhea and neuralgia are frequent.

CONCLUSIONS FROM THESE OBSERVATIONS.

A careful analysis of the cases shows that if an attempt is made to find in acute or chronic morphinism and cocainism any of the well-known forms of psychosis, a total failure follows. Some cases may simulate melancholia, mania, manic-depressive insanity and even paranoia, but in none of them can be found the typical pictures of these psychoses.

Outside of the special tactile hallucinations of cocainism, we find in the acute form sometimes a delirious or a stuporous state. An element of confusion always accompanies them. Hallucinations of sight and hearing are frequently present.

In the chronic form, the most important part of the present study, the part which gives us the most concern, we do not find any of the above-mentioned psychoses in their typical forms, but we do find vague manifestations, as delusions of a transient, fleeting and fragmentary character. It is true that at certain periods of their evolution the latter assume the form of systematized ideas and conceptions, reinforced by hallucinatory images, and thus may present a picture of paranoia or other forms of insanity, but the *ensemble* of the condition does not permit us to consider them as such.

A characteristic symptom is the gradually oncoming dementia, which develops very insidiously in the inveterate habitués and increases with years until a complete psychic decrepitude is established. It is this threatening progressive quantitative diminution of mental power that presents the alarming problem for us when we are called on to counsel and render assistance to the community.

When we compare intoxications from other sources with that of our present study we do not find any essential difference. Each agent may add a new special symptom, as, for example, the tactile hallucinations of cocainism, but the fundamental clinical picture in all remains invariably identical. In the acute forms there is a confusion of all sorts of mobile and contradictory conceptions, a dissociation of all elements of normal psychic life. Hebetude, stupor and amnesia follow. These manifestations may be accompanied by hallucinatory images and sometimes superimposed by incidental delirious states. Not infrequently is observed the *"rêve onirique"* on which Régis lays so much stress. That is to say, a dreamy state which is the continuation of dreams occurring during the night. The images seen by the patient in his dreams are confused with the impressions of real life and thus increase the contradiction of conceptions.

In the chronic form all varieties of intoxications invariably lead to the gradual enfeeblement of mentality, viz., dementia.

SUGGESTIONS FOR LEGISLATIVE AND OTHER MEASURES.

The disastrous effect of chronic absorption of morphin and cocain is well known not only to physicians, but also to the laity. The physical and intellectual disintegration to which the pernicious habit leads is a menace to society. The unfortunate characteristic feature of the condition is that when morphin or cocain have been taken for a certain time, they become an imperative necessity to the organism, inasmuch as when being withdrawn the function of each organ is disturbed. The patient seeks then instinctively to supply the want by repeating the initial dose, at first only in small amounts, but later in larger doses. When the habit is established, it is by far more difficult to overcome than that of alcohol. De Quincey, in his "Confessions," states that he used opium for fifty-two years. Four times he attempted to give it up, but only for a short while. Finally he broke himself off forever. "I triumphed," he says, "but infer not, reader, from this word triumphed a condition of joy; think of me as one, even when four months had passed, still agitated, writhing, throbbing, palpitating, shattered."

We can not ignore the fact that while morphinomania or cocainomania used to be known mainly among physicians (according to Lacassagne's statistics over 50 per cent.) and persons coming in contact with drugs by virtue of their occupations, are now spreading to all classes of society. Daily reports of newspapers and statistics prove conclusively the truth of this observation.

In attempting to remedy the growing menace, it should be borne in mind that *morphin is a precious* remedy in certain incurable affections (cancer, for example), accompanied by *atrocious and intolerable pain.* In such cases the patient must be supplied with the drug *ad libitum.*

The struggle, therefore, will be confined to those cases in which the passion for morphin or cocain is acquired outside of painful conditions. In such cases, as is well known, the craving and longing for the drugs develop only after a more or less prolonged period of use. Interference at the proper time, therefore, may be of great utility in the majority of cases.

As *prophylaxis* is the most efficient measure, some legislative acts rigidly enforced will prevent at least the extraordinary propagation of one of the most pernicious habits—which eventually leads to physical and especially mental decrepitude as depicted in the histories of my cases.

In my judgment, no pharmacist or chemical house should dispense the drugs to any person without a physician's prescription. The latter must be written plainly and the order given only once. When a renewal of the drug is necessary, another prescription must be given by the physician. Of course, no attempt should be made by legislature to limit the prescribing physician to a certain dose of the drug or to a certain number of renewals, as it may interfere with the administration of the drugs in cases in which human suffering is intense. This matter should be left entirely to the physician's moral responsibility.

Heavy penalty with imprisonment should be imposed on those who will sell or give away the drugs without regular prescriptions. Heavy penalty with imprisonment should be imposed on those who will forge a physician's prescription.

Besides a legislative prophylaxis there is a medical prophylaxis. Morphinism usually occurs in individuals with a special make-up of their nervous system. Such persons present deficiency of the intellectual and moral faculties. In them the deficient inhibitory power becomes an easy prey for all abnormal tendencies, particularly for morphinism or cocainism. The latter are the result of a neuropathic constitution, the fruit of hereditary tendencies.

In handling such individuals, one should remember Ball's dictum, to wit: "Morphinomania is entered by the door of pain, of sexual passion, of sorrow, also by the door of contagion, viz., imitation."

THE QUESTION OF RESPONSIBILITY.

We have seen above what order of mental disturbances are present in acute and chronic intoxication.

In the *acute* form, mental excitement, delirium and hallucinations with incoherence are the usual psychic manifestations. They resemble, therefore, the symptoms of acute alcoholic intoxication. When a criminal act is committed by an individual who is in a delirious state and has hallucinations, who is then incapable of distinguishing between right and wrong, whose cerebral functions are then in a state of dissociation, such an individual can not be considered responsible for his acts from a medical standpoint.

When the patient is only in a state of mild agitation, without a delirious or hallucinatory state, or in a mildly stuporous condition, the responsibility is complete. Partial responsibility should be admitted when the patient has recovered from the immediate effects of acute intoxication, but remains for weeks, as we have seen in some of my cases, mentally dull, apathetic, with lack of sustained attention and difficulty of comprehension.

In the *chronic* form of morphinism and cocainism the impairment or disappearance of the moral sense, deficiency of the will power and even a mild diminution of intellectual faculties do not entirely exempt a morphin habitué from responsibility; the latter is only partial. When delusive ideas or hallucinations are present, the irresponsibility is total.

When the patient reaches the stage of dementia, even in the absence of delusions, he can not be held responsible for any of his acts.

Sweat Secretion in High Altitudes.—H. Sewall, in *Colorado Medicine*, states that the technical difficulties in the way of determining the relation of altitude to secretion of perspiration are very great. It is commonly stated by those who guess at facts that the circulation in the skin and the activity of the sweat glands increase with the elevation above sea level. Mosso found, on the contrary, that a resting man loses weight more slowly from the skin on the mountains than at sea level. Zuntz found that exercise at a moderately high elevation—1,740 feet—produced more abundant sweating than in Berlin.

REMARKS ON THE FEEDING OF THE HEALTHY INFANT.

JOSEPH BRENNEMANN, M.D.
Assistant Professor of Clinical Pediatrics, Northwestern University Medical School.
CHICAGO.

During the last decade the problem of infant feeding has been a peculiarly interesting one in this country. While European writers are fairly well agreed on fundamental methods, there has grown up a system of infant feeding in this country that in its elaboration is unique. This so-called percentage, or American, system has received such universal and unqualified approval among our pediatricians that it seems almost like heresy to doubt its tenets, and yet an overwhelming mass of evidence has appeared in the last few years that to my mind discredits the fundamental principles of that system.

I shall first outline what I believe to be a rational dietary for the first year of life and will then advance briefly some objections to the percentage method. It is important at the start to define the term "healthy" baby, because there is an essential difference between a healthy and a sick baby in its reaction to food. This difference centers in one fact—a normal, healthy infant has a broad tolerance for widely different food mixtures and for varying amounts and strengths of the different food elements, fats, proteids and carbohydrates. On the other hand, a baby that is congenitally below par, or that has been damaged by unwise feeding, or that has a temporary nutritional or digestive disturbance due to some intercurrent infection such as pneumonia, has a narrow range of tolerance for food. The sick baby requires careful dosage of food both as to quantity and composition. The moment a healthy baby is upset it is no longer a healthy baby but a sick one and must be treated as such. A food of a certain quantity and composition that yesterday was adapted to a healthy infant to-day may act as so much poison to the same baby that in the meantime has had an acute digestive or nutritional or constitutional disturbance.

THE QUESTION OF ARTIFICIAL FEEDING.

The most serious question that confronts the physician in the feeding of healthy infants is what to feed a new-born baby that is unable to get mother's milk. Budin, who was second to none in the value of his experience in infant feeding, says: "We, ourselves, and we say it in all sincerity, can not as yet indicate from our personal experience what is the best method of procedure in artificial feeding from the start." In practice he answered the question by making sure that nearly every baby in his care had mother's milk for a time. The value of the latter, even if used only for a short time, can hardly be overestimated.

Practically, it will be found that the great majority of new-born babies will bear well after the second day of life—and no baby should be fed artificially before that time—a dilution of one part of milk with two parts of water, with the addition of a small amount of milk sugar, say one-quarter to one-half an ounce in the twenty-four hours' food. This dilution can be strengthened gradually till the baby takes equal parts of milk and water with one-half to one ounce of milk sugar daily during the second and third months. The proportion of milk is gradually increased, that of water and sugar diminished till toward the end of the first year the child is rarely exceed one quart. After the fifth or sixth month the ability to digest starch is so well established that the diluent of water is replaced by one of the cereal waters, or gruels. In the latter months of the first year additional food is given in the form of broths, strained vegetable soups, beef juice, fruit juice, zwieback, cracker, cereals, etc.

FREQUENCY OF FEEDING.

At no time during infancy is it desirable to feed the baby more often than five or six times in the twenty-four hours, and toward the end of the first year the number should not exceed four. This gives approximately a four-hour interval between feedings, and I believe that this interval, in the great majority of cases, should obtain from the start. It is a well-established fact that the stomach of a baby fed on cow's milk is not emptied till at least three hours after feeding. To feed a child oftener than, say, every three hours necessarily favors retention and the formation of fatty acids and is the cause of much of the indigestion that goes with early artificial feeding. Observation on any normal infant for the first few months of life that is digesting its food well will demonstrate the fact that naturally it will go as long as from three to five hours between feedings. It is a common experience that a baby fed at the breast every two hours will nurse well only every second time, while it can hardly be roused from its sleep the other time. The custom of feeding a bottle baby every two hours, that is still the rule for the first few months, has certainly no foundation in theory, and it can be demonstrated practically in nearly every baby that it is unwise to refill a stomach at the end of two hours when it is only partly empty. It is my experience that babies fed every four hours cry less than those that are fed every two or three hours, for the simple reason that babies cry far more from digestive and nutritional disturbances than from hunger.

THE QUANTITY OF FOOD.

The question of how to feed a baby is only partly solved when we have decided what it shall get and how often; there still remains the great factor of how much the child shall get. Our text-books, unfortunately, give us but little help in this, because they lay every stress on the strength or percentage and not on the total amount of food. A number of continental writers, notably Biedert, Heubner and Budin, have emphasized the great danger of overfeeding and each has attempted to show how to avoid it. It remained, however, for Czerny and Keller to show us just what happens when a healthy baby gets too much milk, and why it happens. This clinical picture of milk overfeeding is not an occasional occurrence—it is the rule. Nearly every baby that is fed milk without some check on the amount given during the twenty-four hours shows it in greater or less degree.

RESULTS OF OVERFEEDING.

When a healthy infant gets more milk than it ought to have it commonly gains for a time at an abnormal rate, say, from eight to twelve ounces a week. This gain in weight is quite regularly followed by a stationary weight unless the amount of food is reduced or changed in a certain way. If the amount of the same food is still further increased there may be another gain, but the child will finally begin to lose. If unchecked the ultimate outcome of this overfeeding is marasmus. This paradoxical loss in weight with an increase in food is accompanied by other signs of a fundamental nutritional disturbance. The child becomes restless, its sleep is broken and it cries a great deal. It becomes pale, flabby and inactive, often rachitic. It has a marked tendency to itching eruptions that vary from the small, rough reddish spots on each cheek to the most extensive universal infantile eczema. It very commonly becomes peculiarly indifferent to its bottle, requiring much coaxing to take it, or in severe cases finally taking only an ounce or two at a time.

This condition of milk overfeeding is always accompanied by a characteristic appearance of the bowel movements which in itself shows that the child has had too much milk. The stools lose their normal yellow color, become pale yellow, or in severe cases have the color and consistency of putty. They are no longer normally moist and soft, but become hard and brittle, so that they will roll from the diaper without leaving it soiled. This condition naturally produces very marked constipation.

TOO MUCH FAT.

Whenever such bowel movements appear it means that the child has had too much milk, or, more properly, too much milk fat, because it has been shown that these bowel movements are composed largely of insoluble fatty acid salts. The resulting acidosis Czerny and Keller consider the cause of the nutritional disturbance that has just been outlined. That the fat alone is the cause of this condition is further shown by the fact that increasing the milk, or the fat alone by adding cream, will heighten the whole clinical picture, while diminishing the fat or eliminating it will produce a return to normal. The proteids and sugar have no part in this clinical picture. This is clearly shown by the fact that these cases improve most rapidly on malt soup, or skim milk, or buttermilk mixtures in which the fat is the lowest, while the proteid and sugar are the highest ever used in infant feeding.

At any time in this chronic process of milk overfeeding the whole clinical picture may suddenly change to one of an acute catastrophe. In many infants these sudden upheavals occur regularly whenever milk is added up to a certain amount. This upsetting, that is so frequent an occurrence in artificial feeding, is manifested clinically by vomiting, indigestion, diarrhea, loss in weight, fever, inability to stand food, especially milk, stupor or restlessness. If the disturbance is severe there are all the evidences of intoxication, including leucocytosis, albuminuria, glycosuria, dyspnea, collapse and especially psychic depression. This condition may vary from a mild indigestion to an intoxication so intense that it is rapidly fatal. The more serious cases occur more commonly during hot weather because the child is already debilitated by the heat, but more especially because it is relatively more overfed because it needs so much less food to maintain its heat and energy.

A METABOLIC DISTURBANCE.

This acute calamity has commonly received the name of gastrointestinal disturbance, summer complaint, summer diarrhea, enterocatarrh, gastroenteritis, gastroenteric intoxication, cholera infantum, etc., and has always been assumed to be due to an intercurrent infection along the gastrointestinal tract. In a series of classical papers appearing in the *Jahrbuch für Kinderheilkunde* during the past six months Finkelstein of Berlin has demonstrated very convincingly that the intoxications that occur in these cases are not due to an infection but to a metabolic intoxication more akin to uremia or diabetic coma, caused by the ingestion of more food than the baby can assimilate. That this theory is a correct one is evidenced by the fact that any degree of indigestion and intoxication can be produced at will in these cases by increasing the food to a sufficient degree, and a return to normal will follow just as certainly when all food is withdrawn for twenty-four or forty-eight hours. Finkelstein has increased the food in several cases without a qualm of conscience, because he knew that a day or two of water-diet would restore the child to its former condition.

It seems to me that in this idea of a metabolic disturbance rather than in a simple infective process we have the only satisfactory explanation for the greater prevalence during the summer months of these digestive and nutritional disturbances that are accompanied by intoxication and have in this a most valuable indication that any infant food must be materially lessened during the hot weather.

This metabolic intoxication follows most naturally and most frequently in the cases of milk overfeeding. Theoretically, then, one would expect the fat to play the chief rôle here as there. These patients, we know from every-day experience, can not take cream nor even whole milk in small quantities for some time, and yet will take skimmed milk almost from the start. A child that is well convalescent can be given a relapse to its former condition by the addition of only a small amount of fat. Finkelstein has shown conclusively that sugar when given in excess, as in buttermilk and malt soup preparations, can produce the same intoxications and, even in small amount, the same relapse, while proteid, whether albumin or casein, can produce neither.

I have dwelt rather at length on these results of overfeeding, because the artificial feeding of healthy infants is a negative as well as a positive procedure. We must see not only that the baby gets enough of each of the food elements, but also that no harm comes to it from unwise feeding. If overfeeding is as important a factor in the causation of digestive and nutritional disturbances as I have indicated, then the prophylaxis of overfeeding is of the greatest importance in the feeding of a healthy baby.

In those babies that one has under satisfactory observation it is a simple enough matter to tell when they are thriving as they should, and almost equally simple to tell when disturbances are arising that are due to overfeeding. A healthy child is a "good baby" unless it is spoiled; it sleeps well, it is contented and active, has a good pink color, its tissues are firm, its bowel movements are yellow, moist, not excessively offensive and well digested; its temperature is remarkably uniform at all times; its gain in weight conforms to what we recognize as a norm, a steady gain of about four ounces a week throughout the year, a little more during the first few months, a little less during the last few months. If too little food is given the gain is insufficient, if it is increased to the proper amount the gain becomes normal. Milk overfeeding is easily recognized by the symptom-complex outlined above.

THE EVIDENCES OF INTOXICATION.

The acute catastrophes or intoxications likewise give their warnings. The prodromata that are always present may be of very short duration, or they may extend over weeks and months and should always be heeded. There is evidence of indigestion shown by the general condition of discomfort and by the character of the bowel movements; the weight curve shows wide variations with a general tendency to remain about level or to go down. Still more important, there is an abnormally variable temperature curve with occasional spurts of fever and an increasingly narrow tolerance for certain food elements, notably the fat and the sugar. If these warnings are heeded and all food is withheld for twenty-four or forty-eight hours while the child is on a water or tea or cereal water diet with saccharin (gr. i to the quart) to sweeten its food the danger is avoided. If unheeded, and especially if the food is increased because the child is losing, the intoxication is almost inevitable.

Fortunately we have certain numerical standards as to the amount of food that the normal infant should get. These figures are the result of observations on large numbers of thriving breast-fed and bottle-fed babies. These standards are of immense practical value in every case, but especially in those cases in which one can not see the patient constantly, not so much to tell us how much to give a baby as how much not to give. They should be considered, therefore, rather as a check on overfeeding and underfeeding than as a guide.

BODYWEIGHT VERSUS AGE.

If simple milk dilutions with the addition of carbohydrates are used the simplest and most natural standard would be one that would tell us about how much milk per pound or kilogram a baby should get. That it is more important, as a general proposition, to vary the amount of milk according to weight rather than according to age is, I think, a self-evident fact. Budin gave us a valuable rule of this kind. He prescribed for every baby after the fifth or sixth month and weighing from thirteen to fifteen pounds one-tenth of its body weight of undiluted milk. This would be the equivalent of about one and one-half ounces to the pound. This standard, if a proper one when straight whole milk is used, is manifestly too high when milk dilutions with the addition of sugar or gruels are given, because here a considerable quantity of food is given outside of the milk itself in the form of sugar or starch.

In such dilutions as I have indicated it has been found that one ounce of milk to the pound of bodyweight is about a minimum on which a healthy baby will thrive as it should; that an ounce and a quarter is the more usual amount, and that we commonly have distinct evidence of overfeeding when we approach one and one-half ounces to the pound. A healthy baby of twelve pounds, therefore, would have at least twelve ounces of whole milk in its twenty-four hour food, more commonly fifteen ounces, and rarely if ever as much as eighteen ounces. It must be distinctly understood that this is not a definite rule applicable to every healthy baby. The important point is that it has been found empirically that the milk requirement of the great majority of healthy babies who are thriving on milk dilutions such as the above lies between one and one and a half ounces to the pound of body-weight. To my mind this simple guide is one of the most useful in infant feeding. It is, of course, of no value in feeding a sick baby, because here the limit of food tolerance is very quickly reached and we can give only as much as the baby can digest and assimilate in its present condition.

THE ENERGY QUOTIENT.

A still more useful standard, because it can be applied to all kinds of food combinations, is the calorimetric standard, according to which the food requirements are expressed in calories per pound, or per kilogram of body-weight of baby. To Heubner belongs the credit of having accurately determined the number of calories per kilogram of body-weight used daily by the healthy, thriving infant. This so-called "energy quotient" he placed at a maximum of one hundred for the first six months, the amount gradually lessening after that to about eighty or eighty-five at the end of the first year. He considered seventy as the approximate energy quotient on which weight equilibrium would be maintained. For several years I have determined the energy quotient in every feeding I have given and I am still daily impressed with the practical value and accuracy of the figures laid down by Heubner.

Only very exceptionally, if ever, is it necessary in healthy babies to exceed these figures. It must be emphasized that one should never determine in advance how many calories to feed a baby of a certain age and weight, but that we feed a baby a food of proper composition, and at proper intervals for that baby, and keep tab on its energy quotient to prevent overfeeding and underfeeding and to give one that sense of security that comes from knowing that the baby is getting about the amount of food it ought to have. Often a very satisfactory gain is made on energy quotients much lower than those determined by Heubner; the amount on which that child is thriving should not be increased no matter how low the energy quotient.

It is not at all uncommon, on the other hand, to find a baby fed on whey, or skimmed milk, or barley water, or condensed milk mixtures, for a long time, with an energy quotient of only thirty or forty, while the baby needs at least seventy to hold its weight. It is impossible to tell in such cases how much food a child is really getting as compared with what it ought to get unless one uses this calorimetric standard.

The process of determining the energy quotient in any given case is a very simple one. It is necessary to remember only a few figures that represent the caloric value of one ounce of each different food used in infant feeding. Thus cream (16 per cent.) has a caloric value of about fifty-four to the ounce; milk, twenty-one; fat-free milk, ten; sugar, one hundred and twenty; flour or cereal, one hundred; cereal water, two or three, etc. To calculate the energy quotient it is only necessary to miltiply the number of ounces of each ingredient of the food mixture by its caloric value, to add the products and to divide the sum by the number of kilograms the baby weighs. If we divide the total number of calories by the number of pounds it will be necessary to multiply this by 2.2 to get the number of calories per kilogram. After a little practice the energy quotient of a somewhat complex food can be calculated in a few seconds even without the use of paper and pencil.

THE PERCENTAGE METHOD.

Nearly all that has been said has been so at variance with what is taught in our text-books, and what is commonly practiced in this country, that the subject can hardly be dismissed without some reference to the percentage method. The percentage method is practically based on the idea that the proteid of cow's milk is the one food element that is difficult to digest, and, on the other hand, that the fat is comparatively harmless and easy to digest. It further assumes that in feeding a baby the important thing in modifying the food is to give the baby a certain percentage of each food element rather than to give it a certain amount of food. As a logical sequence to this certain tables are set forth that indicate what strength of food a healthy baby should have at different months, the percentages gradually increasing as the infant grows older.

That the proteid of cow's milk is difficult to digest by infants it seems to me has no longer any positive evidence to support it and is discredited by nearly all Continental writers. For a number of years some of us have looked in vain for any clinical picture that we could designate as proteid indigestion. There is a purely theoretical consideration that casein must be hard to digest, because relatively so abundant in cow's milk, because it curdles in large firm masses instead of the finer ones of mother's milk, and because curds that are assumed to be casein are found in the bowel movements as evidence of indigestion. This theoretical consideration has no standing when it can be demonstrated practically that nearly any baby can digest a high percentage of pure casein in suspension, or skimmed milk, provided it can stand that much sugar, and that curds never appear in the stools no matter how great the percentage of proteid, provided the food is fat free, and lastly that curds regularly appear in the stools of babies to whose food whole milk is added even in small quantities after they have been on a fat-free milk. The very curds that have been assumed to be casein, we are now told on the highest authority, are chiefly fat derivatives.

On account of the complexity of proteid metabolism it would seem, theoretically, that an excessive amount of proteid would make a greater demand on both the digestive and metabolic powers of the child than the other food elements. To what extent this is true can not be told at the present time. There is very little if any evidence at the present time that there is any harm in feeding a large amount of proteid, although the fact that Nature provides for so little in mother's milk would make us hesitate to use an excessive amount. It is certainly an interesting fact in this connection that in the cases of severe intoxication, where digestion is nil, and where there is a state of "metabolic bankruptcy" (Finkelstein), proteid alone can be fed, in what would usually be considered excessive amounts even in health, without any detrimental effect, while the administration of small amounts of fat or sugar would surely produce serious results. In two cases of summer diarrhea with profound intoxication, and the patients seemingly moribund, each was given, after one day of water diet during the next twenty-four hours, the pure washed casein in suspension of sixteen ounces of milk. This was followed by an uninterrupted convalescence and curdless bowel movements. Formerly I would not have dared give them even one ounce of milk for a number of days on account of the fear of "proteid indigestion," and I feel positive that both babies would have died if they had been put on barley water with sugar, or on whey, or on milk containing fat.

That fat is relatively easy to digest and metabolize seems equally doubtful. It is certainly the one cause of milk overfeeding and plays the leading rôle in the intoxications, and these two conditions are much the most frequent and serious nutritional disturbances in infancy. We all know from every-day experience that cream is not well borne by sick babies, especially those that have a digestive disturbance, nor is whole milk so well taken as skimmed milk, and if this is true, then there is every reason to believe that the fat is comparatively difficult to digest in health as well. All through our literature we see more and more evidence of the fact that fat is no longer considered so easily digested and assimilated as was formerly thought. The following case is instructive in this connection:

AN ILLUSTRATIVE CASE.

History.—Baby B., aged nine months; weight, eighteen pounds; healthy and thriving on equal parts of milk and barley, water and sugar. The proteid was increased to 4 per cent. within four days; the fat remaining the same (2 per cent.) and the caloric value approximately the same (energy quotient=90). No deviation from the normal gain, digestion and well-being during the following week. During the following ten days the fat was increased to 4 per cent., the proteid lowered to 2 per cent. and the same caloric value maintained. Within a few days practically every symptom of overfeeding was produced, including a universal eczema—which the mother interpreted as measles—anorrhexia, restlessness, pallor, loss of twelve ounces in two weeks, hard gray bowel movements, and finally the fever, frequently cheesy bowel movements, etc., of a beginning intoxication. The fat was then at once lowered to 2 per cent., the proteid increased to 4 per cent., the caloric value remaining the same. Within a few days the child was normal again in every way. Such an experiment is justifiable only because we have a positive assurance that a rational therapy based on our knowledge of the pathogenesis of overfeeding will quickly restore the child to its former condition unharmed.

The assumption that the percentage of different food elements is of prime significance is equally untenable. If the child can only retain and digest it, it makes little difference what the strength of the food is, but it does make all the difference between failure and success whether the child gets a proper or an excessive amount of food. One can as easily overfeed a baby on a large amount of a low percentage of everything as on a much smaller amount of a stronger food. In other words, the percentage of food elements *per se* has no bearing on overfeeding or underfeeding. With the high percentages of fat commonly advocated by those who use the percentage method we have, furthermore, the use of a maximum amount of the one food element that is the important factor in producing the nutritional disturbances that result from overfeeding, i. e., the fat.

Moreover, a study of the tables given in our leading text-books will show that from a calorimetric standpoint they uniformly recommend or permit excessive amounts, especially during the latter part of the first year. For a baby of six months weighing, say, fifteen or sixteen pounds, Holt's table permits an energy quotient varying from 95 to 150, while a proper amount would be 80 to 90 or 95.

It is interesting in this connection, too, to bear in mind the simple fact that mother's milk varies but little in composition or percentage after the first few weeks, but that its amount varies directly in proportion to the needs of the nursling.

It is claimed for the percentage method that it is unique in its flexibility, permitting us to increase or diminish individual food elements at will. With the proteid as a practically negligible quantity in therapeutic amounts it is evident that the other food elements, the fat and the carbohydrates, can be varied just as freely in the use of simple milk dilutions.

Finally, it must be admitted that the percentage system has always seemed a peculiarly complicated one to the great majority of physicians and that most of them ultimately did not use it as taught by those most conversant with it. If not used as intended it permits of a wide range of error. Frequently cream is added in excessive amounts without calculation of either the amount or the percentage and the inevitable bad results follow. It is little wonder, then, that a majority of physicians finally use the simple modifications recommended by the "baby food" men, and this alone is a serious arraignment of that system.

In conclusion, I wish to express my indebtedness to Dr. F. X. Walls for his very kind assistance in many ways.

4549 Indiana Avenue.

CLINICAL OBSERVATIONS ON ANTIGONOCOCCIC SERUM.

ALEXANDER A. UHLE, M.D.
Instructor in Genitourinary Diseases, University of Pennsylvania. Assistant Genitourinary Surgeon, Philadelphia General Hospital. Special Assistant, Surgical Dispensary, German Hospital.
AND
WILLIAM H. MACKINNEY, M.D.
Assistant Surgeon, Genitourinary Dispensary, University Hospital.
PHILADELPHIA.

In October, 1907, a quantity of antigonococcic serum was placed in our hands by Parke, Davis & Co. for experimental use in the treatment of gonorrhea and its complications. This serum is prepared according to the directions of Dr. Torrey and consists of serum obtained from the sheep, immunized against several strains or varieties of gonococci. For an account of the experimental work and the technic employed in the manufacture of the serum we refer the reader to articles by Drs. Torrey and Rogers[1] and a further communication by Dr. Rogers and Dr. Torrey.[2]

The serum is supplied in sealed bulbs of 2 c.c. capacity, and this quantity is recommended as a dose, to be injected hypodermically into the loose cellular tissue of the back, buttock or arm. In our experiments we have never used, except in one case, a larger single dose than 2 c.c., the intervals between injections varying from one to three days. The injections were given deeply into the buttock, as a rule, but in a few cases the interscapular region or the loose tissue on the back of the arm was selected. Our experiments were carried out on a series of twenty-three cases, twelve of which were confined to the hospital and therefore under better supervision than the remaining number which, with one exception, were ambulant cases. The following is a brief report of the history and course of each case:

CASE 1.—The patient, C. I., had gonorrhea two years ago, with recurrences at intervals and acute exacerbation two weeks before admission. There was a mucopurulent discharge in which gonococci were found. The first glass was cloudy, second glass clear. The prostate was enlarged, soft and tender, but not nodular. Gonococci were found in the expressed secretion after irrigation of the anterior urethra. The first injection was made Oct. 16, 1907, consisting of 2 c.c. of serum into the buttock. The injection was repeated in four days and all other treatment discontinued except massage of the prostate. The third and last injection was given three days later. There was less discharge, but gonococci were still present in the expressed secretion of the prostate. On Oct. 24, 1907, the patient refused to remain for further treatment. There was less discharge, but otherwise the condition was the same as on admission.

---

[2] THE JOURNAL A. M. A., Sept. 14, 1907, xlix, 918.

Case 2.—The patient, R. E., had gonorrhea twenty years ago and again five years ago. Since this time he frequently observed a mucoid discharge especially after drinking and intercourse. Examination revealed a slight mucoid discharge and many shreds in the first glass of the two glass test. Many large shreds were present in the third glass after massage of the prostate. No stricture was present. The right lobe of the prostate was large and tender; the left lobe was not markedly enlarged, but tender. Gonococci were found after several examinations of the expressed secretion. The patient had been treated for three months with but slight improvement before the first injection, which was given on Oct. 16, 1907. All other treatment was then discontinued except massage of the prostate twice weekly. He received nine injections in all, given every other day. There was no improvement in his condition and gonococci were present when this treatment was discontinued.

Case 3.—The patient, M. P., had a negative past history. The duration of his condition before admission was three months. The patient developed a left epididymitis in the tenth week. Examination revealed a large, painful and tender epididymis, slight mucopurulent discharge, both urines cloudy, and gonococci present. On date of admission, Oct. 28, 1907, the patient was put to bed, the scrotum elevated and an injection of serum given into the buttock. The injections were repeated daily until November 9, with a gradual improvement in the condition. The pain and tenderness had subsided, a discharge was still present and both glasses of the two glass test were cloudy. The injections were discontinued and other treatment instituted.

Case 4.—The patient, W. S., had a negative past history. The duration of his condition was seven days before admission, Oct. 31, 1907. There was a profuse purulent discharge, first glass cloudy and second glass clear, gonococci present. Six days after the patient's admission there developed a painful and tender swelling in the calf of the right leg, extending from a few inches above the ankle almost to the popliteal space. The patient could not walk on account of the pain. A probable gonorrheal myositis was diagnosed and serum treatment instituted, the injections being repeated every third day. On the day after the second injection there was less swelling, but considerable pain and tenderness persisted. After five injections had been given the swelling had almost disappeared, but pain and tenderness were still present. Bier's hyperemic treatment was then applied every day, and the injections continued every third day until November 30, when all local evidence of inflammation had disappeared. During the treatment the urethral discharge ceased, and only a few shreds were present in the urine. An astringent injection was given and caused a reaction, and gonococci were demonstrated in the discharge.

Case 5.—The patient, L. L., had gonorrhea two years ago. The present attack was of five weeks' duration. There was a purulent discharge, gonococci were present. There was frequent, imperative urination and both glasses were cloudy. The left ankle began to swell two weeks after the onset of the acute attack. The joint was swollen, very tender and painful. The first injection was given the day after admission, Nov. 6, 1907. Bier's treatment was used in conjunction with rest and elevation. Patient received six injections in all, every third day. The day following the third injection the joint was but slightly swollen, there was no pain or tenderness, and the acute urethral symptoms had ceased. After the sixth injection there was no evidence of local inflammation. The urethral discharge, however, persisted.

Case 6.—The patient, J. D., had gonorrhea five years ago. He was admitted Nov. 19, 1907, suffering from acute gonorrhea of four days' duration. There was a marked purulent discharge, and gonococci were present. The first glass was cloudy and second glass clear. Patient received first injection on the day after admission. Three injections were given during a period of one week. There was no improvement in his condition and he was referred to the dispensary, but failed to report.

Case 7.—The patient, C. C., had gonorrhea five years ago. The present attack was of four days' duration. There was a purulent discharge, the first glass was cloudy and second glass clear; gonococci were present. The patient was given an injection every day for one week, at which time there was no improvement and he refused further hypodermic medication.

Case 8.—The patient, J. D., had gonorrhea ten years ago and several recurrences since. The duration of the present attack was three weeks. There was a purulent discharge; the first glass was cloudy and the second glass clear; gonococci were present. The patient was referred from the medical wards, where he had received treatment for supposed rheumatism confined to the back and right hip. Patient complained of severe pain in the back and right hip and walked with difficulty, but there was no local evidence of inflammation. Injections were given every other day, six in all. There was less discharge; the urine remained the same and gonococci were present. There was no relief from pain. Serum treatment was discontinued.

Case 9.—The patient, W. J., had a negative past history. The duration of the present attack was two weeks. There was a moderate purulent discharge; both glasses were cloudy, and there was frequent imperative urination. There was a right epididymitis of six days' duration and a left epididymitis of three days' duration. Gonococci were present in the discharge. On Nov. 13, 1907, the patient received the first injection. There was no other treatment except rest in bed and elevation of the scrotum. On November 16 the patient complained of slight pain and tenderness. The swelling rapidly disappeared on both sides; the discharge remained the same. The patient received a second injection November 19. There was no pain or tenderness; a slight swelling remained; the discharge was the same. A third injection was given on November 22. A small nodule was present on each side. A fourth injection was given on November 26. All symptoms of posterior urethritis having disappeared, serum treatment was discontinued and the patient was referred to the dispensary for further treatment.

Case 10.—The patient, M. M., had a negative past history. The duration of his present attack was three weeks. The patient was admitted to the hospital Oct. 29, 1907, with a purulent urethral discharge, in which gonococci were present. There was frequent, imperative urination and both glasses were cloudy. Daily irrigations, together with internal balsamic treatment, were given until Nov. 21, 1907, with but slight improvement. On this date the first injection was given and all other treatment was discontinued. Two days later another injection was given and injections were repeated every second day until five injections had been given. In this patient there was a marked improvement from the beginning of the serum treatment. The discharge became less, and, after the third injection, ceased entirely. After the fifth injection the urine was perfectly clear.

Case 11.—The patient, A. E., had a negative past history, and a gonorrhea of three weeks' duration. He developed a right epididymitis two weeks after the urethral discharge was first noted. At the time of admission to the hospital there was a slight mucopurulent discharge in which gonococci were found; the first urine was cloudy and the second slightly cloudy. The epididymis was very large, painful and tender. On Nov. 25, 1907, the date of admission, the patient was put to bed, the testicles were elevated and an injection of 2 c.c. was given into the buttock. In three days there was no pain, slight tenderness and the epididymis was almost normal size. Another injection was given, and repeated in three days. At this time only a small nodule remained. There was no return of the discharge, and the first glass of the two glass test contained only shreds. The serum treatment was discontinued.

Case 12.—The patient, J. S., had no previous history of venereal disease. The patient first noted a discharge Nov. 4, 1907, and developed a right epididymitis Nov. 13, 1907. He was admitted to the hospital on November 20 with a purulent discharge, frequent urination and a large, painful swelling of the right epididymis. Both glasses were cloudy. He was given an injection on day of admission, and the treatment was repeated daily for four days, without making the slightest improvement in his condition. It was necessary to give him anodynes every night on account of the pain. The serum treatment was discontinued, and wet dressing of a saturated solution of magnesium sulphate applied. All pain disappeared in four hours.

Case 13.—The patient, J. G., had gonorrhea six years ago and came to the dispensary of the German Hospital with gonorrhea of three weeks' duration. He complained of frequent imperative urination and both glasses were cloudy. He was given five injections, each of 2 c.c. serum on every second day. No other treatment was given. As there was no improvement in his condition, and as he objected to further hypodermic medication, other treatment was instituted.

Case 14.—The patient, C. R., had gonorrhea of seven weeks' duration, and left epididymitis of five weeks' duration. He had a slight discharge containing gonococci. The epididymis was not painful, but large, hard and indurated. The first glass was cloudy, the second clear. He received four injections at intervals of three days. No improvement was noted. He objected to further hypodermic medication.

Case 15.—The patient, E. K., had a gonorrhea of three months' duration and a left epididymitis of one month's duration. When first seen in the dispensary there was a slight purulent discharge, the epididymis was slightly tender, large and indurated. Both urines were cloudy. The patient complained of marked pain in the left ankle, which was not swollen but tender to pressure. The left wrist joint was very painful, tender and slightly swollen. The pain in the joints was noted three days before coming to the dispensary. The patient received the first injection Dec. 16, 1907. On December 20 his condition was the same and he received his second injection. On December 23 his urethral condition was the same; there was no pain in ankle, but a slight tenderness; the epididymis was somewhat smaller. Another injection was given. On December 27 there was no pain or tenderness in ankle; a slight tenderness only on pressure in wrist joint. Otherwise the patient's condition was the same. On December 30 there was no evidence of articular involvement. On January 3 there was a slight mucopurulent discharge containing gonococci; the first glass was cloudy and the second clear. The epididymis was still large and indurated.

Case 16.—The patient, J. T., had a negative past history. He came to the dispensary November 18 with a profuse purulent discharge of four days' duration, the first glass was cloudy, the second clear. An injection of 2 c.c. serum was given. On November 20 no improvement was seen and a second injection was given. On November 23 there was a profuse purulent discharge, with edema of prepuce and chordee. The patient requested other treatment, refusing further hypodermic medication.

Case 17.—The patient, J. L., had gonorrhea eight years ago. The duration of his present condition was two weeks. There was a profuse purulent discharge, chordee, and left epididymitis of one days' duration. A suspensory bandage was applied and an injection of serum given. On November 24 the patient's condition was the same, and a second injection was given. The patient was not observed again for six weeks. He then returned to the dispensary for treatment of urethritis. In the interim he had sought treatment elsewhere and the left testicle had been removed.

Case 18.—The patient, F. S., had a negative past history. The duration of his present condition was eight months. The meatus was small, there was a purulent discharge, no urinary frequency, both glasses were cloudy. On November 18 an injection of 4 c.c. serum was given. The patient did not return to the dispensary until December 2. There was no discharge, and both glasses were clear. The patient denied taking any other treatment. On December 16 there was no discharge, the first glass contained a few shreds. No gonococci were found. The patient did not return for further observation.

Case 19.—The patient had a gonorrhea of three weeks' duration. There was a profuse purulent discharge and marked local symptoms; gonococci were present. There was no urinary frequency, the first glass was cloudy, the second clear. On December 16 an injection of 2 c.c. was given and the treatment repeated every day until five injections had been given. On December 22 there was no improvement; the disease had extended to the posterior urethra. The serum treatment was discontinued.

Case 20.—The patient, G. E., had gonorrhea eight years ago and again four years ago. The duration of his present condition was one month. There was a purulent discharge containing gonococci and frequent imperative urination. The prostate was large, tender and soft. Both ankles and the right knee were acutely inflamed. On December 14 an injection of 2 c.c. of serum was given, and the treatment repeated daily for six days. There was then an entire absence of articular involvement. The urethral and prostatic condition remained the same.

Case 21.—The patient, W. W., had had gonorrhea for seven months. There was a mucoid discharge and the urine was full of shreds. Gonococci were present in the prostatic secretion obtained by massage. On November 21 the patient received the first injection, and all other treatment was discontinued except massage of the prostate per rectum. Nine injections in all were given in the following fifteen days. There was no improvement and the serum treatment was discontinued.

Cases 22 and 23.—These were dispensary patients suffering with subsiding urethritis, presenting a mucopurulent discharge and shreds in the first urine voided. Each received two injections at intervals of three days, but neither reported for further observation.

Of the twenty-three patients treated, patients 1 to 12 inclusive were confined in the hospital, all the others, with the exception of patient 20, were ambulant cases. All of the patients suffering with acute inflammatory complications who were treated in the hospital, and patient 20 as well, were confined to bed. Regarding the action of the serum on the urethral infection, it appears that it has little if any curative action. The improvement in the urethral condition in some patients may be attributed more to rest and hygienic treatment than to any specific action of the serum.

None of the patients suffering with gonorrheal prostatitis was cured. Of the seven cases of epididymitis, improvement was observed in three, no improvement in four. These three patients were confined to bed, with elevation of the scrotum, and it is doubtful if the improvement can be attributed to the serum alone. As is well known, many patients suffering with epididymitis are relieved of acute symptoms when confined to bed and receiving no treatment other than elevation of the scrotum.

If conclusions can be drawn from this limited number of cases, it appears that neither the number of injections nor the time elapsing between injections has any influence on the results of the treatment, as in no case was there what might be termed a prompt improvement, which is to be expected from an antitoxin treatment. Possibly better results would have followed the administration of larger doses.

The best results were obtained in the patients suffering with arthritis. Three were promptly relieved and all local evidences of inflammation had subsided in less than two weeks. In one of these Bier's treatment was used in conjunction. As is well known, gonorrheal arthritis is one of the most obstinate conditions to cure, and such prompt relief as was obtained is encouraging. With no other treatment excepting opsonotherapy and Bier's treatment have such gratifying results been obtained. In the case of the patient complaining of pain in the hip and back it is questionable whether the pain was gonorrheal in origin, there being no evidence of articular inflammation.

The patient with gonorrheal myositis showed but little improvement after two weeks' treatment with serum alone, but responded promptly when Bier's treatment was used in addition.

Following the use of the serum injections a general urticarial eruption was observed in seven patients. Other than slight pain at the site of the injection and the urticarial eruption, accompanied by the most intense itching, no local or general toxic manifestations were observed.

1831 Chestnut Street.

ELEMENTS OF PSYCHIATRIC PROGNOSIS*

F. X. DERCUM, M.D.
Professor of Nervous and Mental Diseases, Jefferson Medical College; Neurologist to the Philadelphia Hospital.
PHILADELPHIA.

The prognosis of mental disease offers, as is well known, peculiar difficulties. These difficulties are due to our lack of knowledge of the morbid agents at work, of their mode of action, of the physical make-up of the patient, and in a still greater degree to imperfect clinical data.

THE ELEMENTS OF THE PROBLEM.

Our knowledge of the first group of facts, namely, of the morbid agents, is in itself most imperfect and is limited to a few of the agents concerned in the insanities of intoxication, to a few concerned in the insanities resulting from infection, and to a still smaller number concerned in the insanities of autointoxication, such as the diathetic insanities and the insanities dependent on thyroid derangement.

Our knowledge of the second class of facts, namely, those dealing with the structural peculiarities of the patient, is still more unsatisfactory; it is embraced in the rather vague conceptions conveyed by the term neuropathy. We can express our ideas concerning the latter only in a general way. A neuropathy means departures in morphology, arrests, deviations affecting the skull, the limbs, the nervous system, the vascular apparatus and other structures; in other words, it means departures from the normal of the organism as a whole. It follows that the ductless and other glands and the tissues generally, each of which contributes its modicum to the various fluids of the body, the blood, the lymph, the cerebrospinal fluid, as the case may be, are involved in the imperfect and aberrant development. It would seem that in neuropathy the conditions present are such as to imply a diminished resistance on the part of the nervous system on the one hand, and a toxic metabolism on the other. Further than such a general expression it is as yet impossible to go, however, and the difficulty of prognosis is still further increased by the great range of variation in individual cases both as to symptoms and course. In individual cases, in consequence, it is usually possible to make only general statements as to probability of outcome and none but the coarsest approximations as to duration.

Of necessity we are compelled to rely on factors purely clinical in their nature. Our clinical knowledge has made great and increasing advances. Since the epoch-making studies of Kahlbaum and Hecker, and especially since the more recent recognition of dementia præcox by Pick and its subsequent expansion by Kraepelin, our conceptions have become more and more clear. This is true not only of the dementia præcox group, but also of the manic-depressive group. Notwithstanding our knowledge, from the very nature of the subject, must continue to lack precision. No measure of exactitude can apply. As a rule, a general statement only as to the outcome may be hazarded and then only as to the outcome from an existing attack. None but very coarse estimations can be made as to duration, and none whatever as to possible recurrences or as to the extent of intervals of mental health. Owing to numerous and complex factors, at present indeterminate and indeterminable, such as the facts of causation and the facts embodied in the neuropathy of the patient, the degree of his resistance and his power of repair, the problem of prognosis must unquestionably remain in given cases very difficult.

The points which enter into the problem are: First, the clinical form assumed by the mental disorder; second, the presence or absence of actual quantitative mental loss; third, the systematization of delusions; fourth, the fixation of symptoms; fifth, age; sixth, sex; seventh, the presence of morphologic or somatic stigmata; eighth, the significance of heredity; ninth, the bearing of social status.

APPLICATION OF DATA TO PROGNOSIS.

Mental diseases can be roughly divided into two classes. The first class consists of those which are essentially neuropathic—that is, autogenetic. This class includes dementia præcox, paranoia, the manic-depressive group and the neurasthenic insanities or psychasthenias. The second class includes those dependent on infection, intoxication, trauma or other extraneous causes—that is, affections which are exogenetic. This class includes many forms of delirium, confusion and stupor.

Obviously these two classes present primarily widely differing factors in prognosis. It goes without saying that the prognosis of the first class is in general terms far less favorable than that of the second and it will serve our purpose best to begin with a consideration of one of the groups of the latter—for instance, the heboid-paranoid group, the groups to which the general term of dementia præcox has of late years been applied. We are all familiar with the statements made by the great exponent of the modern view of dementia præcox, Kraepelin, regarding the probabalities of recovery in hebephrenia, catatonia and in dementia paranoides. The proportion of recoveries given by him for hebephrenia, namely, 8 per cent., and for catatonia, 20 per cent., I believe to be too low. There can be no doubt that if the milder extramural cases were included the proportion of recoveries would be higher. However, even if we had definitely determined the average proportion of cases of recovery, this of itself would be of but little value in the prognosis of individual cases. Unfortunately also the attitude of physicians in regard to dementia præcox is such as to negative a consideration of individual prognosis, for the very name of the affections implies an unfavorable outcome. Nevertheless, the remarkable improvements, not to speak of the complete recoveries now and then observed, both in hebephrenia and catatonia and even in paranoid forms, make it imperative that each individual case be studied for itself. The question arises as to the principles that should here be applied.

The members of the heboid-paranoid group, hebephrenia, catatonia and paranoid dementia, are so closely related that they can safely be considered together.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

If the first of the list of factors, namely, the form assumed by the mental disorder, be now applied, it is noted, of course, that the presence of catatonic symptoms lends a more favorable aspect to the prognosis than does hebephrenia, while dementia paranoides is the least favorable form of all. This result is, however, of general value only.

On the other hand, the second factor, namely, that as to the presence or absence of quantitative mental loss, that is, of true dementia, furnishes a test which, when it can be applied, is of very great value. Its application is often very difficult, and yet if certain elementary facts be borne in mind the application frequently becomes possible. As I pointed out some two years ago in a paper read in Baltimore, in both hebephrenia and catatonia, it is confusion and not dementia which dominates the clinical picture. All of the elements of confusion are present, hallucinations and illusions, associated with fugitive, changing, unsystematized delusions. In periods of excitement this confusion may attain the intensity of delirious episodes, or, on the other hand, it may deepen, as it habitually does in catatonia, into stupor. Delirium, confusion and stupor are, of course, closely related states, and that they may occur in varying degrees in hebephrenia and catatonia, is, of course, a matter of common experience. The element of confusion in dementia præcox is habitually lost sight of in the discussion of the subject.

Because of the name we habitually think of dementia præcox as a disease which is a dementia primarily and of which the dementia is the most prominent feature. Let us see whether the facts really justify such a position. If we compare the symptoms presented by a case of unquestionable dementia, such as a senile dementia, with the symptoms presented by a case of dementia præcox, we note striking differences. The use of the term "dementia" should be limited to a quantitative change of mind, that is, to the loss of faculty and not to a mere change of quality or change in the mode of action. In a case of simple senile dementia, that is, a case uncomplicated with hallucinations or delusions, we find in the very beginning an impairment of memory, an impairment which makes itself evident at first in the failure to remember how the daily tasks that make up the life of the individual are to be performed, in forgetfulness of the daily duties, obligations and proprieties. As is well known further, this loss of memory involves at first recent events, those which have made the least profound impression upon the mind. It is hardly necessary to dwell here on the characteristics of this impairment. We need only recall the loss of names of common objects, the names of intimate friends and relatives, of the needless repetition of statements, of the garrulousness of old age. No comment is necessary to illustrate these well-recognized inroads into the mental integrity. Professional attainments, languages, the whole of the acquired knowledge of the middle and finally the adolescent periods of life are lost, leaving nothing but the acquisitions of earliest age and sometimes not even these. Compared with this condition of memory, that which obtains in dementia præcox is strikingly different. Disorders of memory are not, to say the least, the initial features of dementia præcox. Indeed, as is well known, memory is, in the beginning and for a long time after the affection has become established, well preserved. It is only after the disease has persisted for a relatively long time that actual loss of memory becomes evident. Further, in dementia præcox, the consciousness of the patient—stuporous states, of course, excepted—usually remains remarkably clear. In true dementia, such as is seen in senile dementia, consciousness, on the other hand, is usually more or less clouded. Still further, in dementia præcox, orientation, a function dependent on the integrity of a great group of complex faculties, is well preserved, the patient being usually in correct relation with his environment—of course, again excepting stuporous states. In dementia, as illustrated by senile dementia, there is frequently gross impairment of orientation, the degree of this impairment being in direct relation to the degree of quantitative mental loss. It is only at a relatively late period that dementia præcox presents changes alike in memory and in orientation. In keeping with this view Regis, Christian, Anglade, Macpherson, Knapp and others classify dementia præcox under confusional insanity.

Many facts also suggest that dementia præcox is due to a toxin or toxins and if so this would bring dementia præcox within the range of the toxic confusions.

The first problem, therefore, presented by a given case of hebephrenia or of catatonia, is to determine the presence of actual mental loss. If such mental loss can not be demonstrated, and if the symptoms of confusion alone are present, the case should be regarded as one in which improvement or recovery is still possible. Under these circumstances we have certainly no right to predicate a necessarily unfavorable outcome.

The determination of the question of mental loss may under given circumstances — that is, in stuporous or deeply confused states—be one of extreme difficulty. However, the mere fact that confusion and stupor are the dominant features lends presumption to the view that they and not dementia are present.

The next point that presents itself is that of the systematization of delusions. Systematization must be considered as a feature apart from fixation, because systematization and fixation do not necessarily go hand in hand. As is well known, systematized delusions that are not fixed constantly occur and, on the other hand, many mental phenomena are met that are fixed and yet do not consist of systematized delusions. The systematization of delusions embraces primarily two distinct factors:

First, in order that delusive ideas should be coherently and logically arranged it is to be presupposed that the mind must have attained a certain degree of development. It is a well-known fact, pointed out statistically years ago by Pickett, that the paranoid cases are found among patients distinctly older than in catatonia or hebephrenia. While in the hebephrenic and catatonic the hallucinatory states are associated with and perhaps give birth to painful delusive ideas, these ideas are not arranged, the suffering of the patient is not logically reasoned out and systematization does not result, although the patient in a vague way presents the paranoid attitude of mind in so far as he projects the causes of his sufferings to sources that are outside of himself. Painful ideas characterized by suffering, torture, poisoning, burning, mutilation inflicted on him, are usually present in such number and such prominence as to dominate the picture and to indicate clearly the reference by the patient of his sufferings to agencies in the external world, and yet systematization is not present. On the other hand, cases are met, both of hebephrenia and catatonia, in which, especially in the older phrenics, the delusions are more clearly paranoid: so much so, indeed, that one is sometimes in doubt whether to classify the case among the hebephrenics or among the paranoid dementias.

It has been the habit to regard cases presenting paranoid delusions as cases in which an unfavorable outcome is foreshadowed. However, it is also a matter of experience that the existence of systematized delusions does not necessarily mean permanency. Time and again it is noted that delusions, though systematized, are poorly systematized and again that they are changeable, manifold and shifting. Time and again improvement and actual disappearance of delusions are noted in such cases. Indeed, even patients in whom a paranoid system of well-defined delusions has been observed may recover. Such a case has been reported by Dewey, and I have myself observed two such instances, one of them during the past year. The patient was a man in the early forties in whom a series of persecutory ideas, associated and possibly based on hallucinations, made their appearance. They persisted for many months, and yet along with an improvement in the general health they disappeared just as completely as do the symptoms of confusion in other cases, the man making a complete recovery.

Another factor to be considered in the systematization of delusions is the intensity of the symptoms. If the mental disturbance be attended by marked excitement and the rapidity of the elimination of ideas be greatly increased, confusion dominates the picture; if the intensity of the disturbance be less pronounced, if, in other words, the confusion is mild in degree, systematization or — perhaps better — pseudo-systematization may be present. Thus the same case of hebephrenia or paranoid dementia may present a varying picture.

In answer to the question whether systematization of itself negatives recovery, or whether it greatly increases the improbability of recovery, it must be admitted that in the larger number of cases systematization must be regarded as a very unfavorable sign. If the delusions lack fixation, however, if they remain ill-defined, and especially if they vary markedly from time to time, the possibility of their disappearance must at least be conceded.

The question of fixation demands special consideration. I am in the habit in my lectures of defining a delusion as a false belief concerning which the person holding it is incapable of accepting evidence—that is, such evidence as is accepted by the average or normal mind. A delusion presupposes some break in association, either temporary or permanent. If the break in association is temporary, such as would be induced by the action of a toxin, the delusions would of necessity be temporary only and we would be inclined to expect a shifting picture of delusive beliefs. It is only when a delusive belief has become fixed that we have the right to conclude that the break in the association has become permanent. It is fixation, therefore, which is the unfavorable sign and not mere systematization. Systematization and fixation, it is true, commonly go hand in hand, but they are not necessarily correlated—not necessarily associated. Fixation, as is well known, occurs in association with other mental phenomena such as those presented by the special forms of fear, by the insanity of indecision, by the defects of will and of inhibition met with in psychasthenias and of which persistence is a well-known characteristic. Fixation in association with systematization of delusions is necessarily a factor of unfavorable prognosis. Fixation greatly lessens the probability of recovery.

The remaining points entering into the prognosis may be considered rather briefly. As regards age, a priori considerations are confirmed by clinical experience, namely, that other things being equal, the younger the individual the greater the possibility and probability of recovery. This can be distinctly claimed for the heboid-paranoid group and it is undeniably true of the manic-depressive group. Cases of hebephrenia or catatonia manifesting themselves relatively late present a greatly lessened prospect of recovery. For instance, in the earlier catatonics, the percentage of recoveries is relatively large; in the late catatonics it is relatively small. As regards the manic-depressive group, it is absolutely true that the prognosis of the individual attacks is infinitely more favorable, especially as regards duration in the younger patients, that is, those of the third decade as compared with those of the fourth and fifth decades of life. How much more prolonged a middle-age melancholia is than a melancholia of early life need not be dwelt on. In general terms, the psychoses met in middle life and old age are far more serious in their outlook both as to duration and eventual outcome than are those of early life.

The sixth point, that of sex, is so extensive as to preclude extended consideration here. Suffice it to say that the relation of the menstrual function to fluctuations in the psychoses must be borne in mind, as must also the unfavorable influence of a prolonged menopause on duration.

The seventh point, the significance of morphologic or somatic stigmata, that is, stigmata indicative of imperfect evolution, next claims attention. Briefly, it may be stated that when markedly present or when present in large number, they are in keeping with defective or aberrant mental development. Again, unless present in marked degree, they have none but indirect bearings on the problem of prognosis, as they are sometimes found associated with entire mental health.

What significance should be attached to the eighth point, namely, that of heredity? That a history of insanity in the ancestry has a profound significance in all cases of mental disease goes, of course, without saying. Sometimes, indeed, it has a special significance as, for example, in melancholia, a disease which occasionally repeats itself with fatal similarity in successive generations. A neuropathic heredity explains in a sense the occurrence of an insanity, but it influences the prognosis of a given attack in only a general way; it can not give us a definite clue as to either outcome or duration. However, it always influences unfavorably the prognosis as to permanency of recovery. Further, it may also influence the prognosis as to the course of an attack. Thus, if neuropathic heredity be pronounced, the course will probably be wave-like, or the symptoms may in other ways indicate a periodic or cyclic course.

The remaining point, that of the social status of the patient, is in given cases of considerable importance. A higher social status implies, other things equal, an ability on the part of the patient to provide himself with better surroundings than those which he can secure in institution life. There can be no question that the prognosis of a given case of hebephrenia or of catatonia is greatly enhanced by circumstances which permit the carrying out of elaborate methods of inducing hypernutrition, that is, methods embodied in absolute rest, full feeding, massage, bathing and the other physiologic methods found so useful in the treatment of exhausted states. The great importance of trained nursing and individual nursing must also be recognized. There can be no doubt, for instance, that the percentage of recoveries and of improvement in hebephrenics is greater under such methods of treatment. Unfortunately, elaborate methods, such as are necessary in a properly conducted rest cure, are expensive and are beyond the reach of the great mass of patients in mental cases.

As regards the class of cases which comprises those not essentially neuropathic, that is, those whose mental disturbance is dependent on infection, intoxication, trauma or other extraneous causes, they present, as is well known, other things equal, a favorable prognosis. Of course, the most favorable are the simple toxic deliriums and confusions. If elements of neuropathy are present these proportionately diminish the favorable outlook.

SUMMARY.

In summarizing the considerations contained in the above paper, I would lay stress especially as of importance in the prognosis of mental diseases on: First, the presence or the absence of actual dementia; second, the presence of systematization of delusions; third, the presence of fixation; and, fourth, the social status of the patient.

The limits of this paper will not permit me to discuss the prognosis of the various clinical forms or even special questions that play an important part in the prognosis. Among the latter may be mentioned the influence of the bodily condition and the significance of visceral complications. In a general way only it may be said that if there be marked physical improvement without corresponding mental improvement, the prognosis becomes proportionately unfavorable. Equally true is the converse, that is, the less frequent condition in which there is mental improvement without physical improvement; such cases should always be regarded with suspicion. Again the marked persistence of hypochondriacal ideas, especially of ideas of somatic and psychic negation, that is, belief in the absence or destruction of viscera, of psychic non-existence, or psychic perpetuity (the belief that the patient is dead or, on the other hand, that he can not die) are not infrequently found associated with chronic and non-recoverable cases.

Special factors, such as interruption and cessation of progress also influence the prognosis unfavorably. Similarly, an incomplete recovery renders recurrence not improbable. Further, one attack presenting a wave-like course raises the presumption of other attacks in the future.

Among favorable features may be mentioned regularity of course, concomitant physical and mental improvement, and, finally, the realization on the part of the patient that he has been ill.

1719 Walnut Street.

DISCUSSION.

Dr. W. T. Williamson, Portland, Ore.: Dr. Dercum is disposed to deprive dementia præcox of the element usually considered the basic fact, that is "dementia," and supply in its stead simply "confusion." It has been rather difficult to separate one form of it, the paranoidal variety, from true paranoia, and the method by which we could, if at all, keep them apart, was by the recognition of dementia of a true type as a feature of the dementia præcox, and the dementia of paranoia, when present, as being simply a pseudo form. The fixity of a delusion depends on the strength of the mind in which it rests. If there is a great degree of dementia present it would appear to be impossible for a delusion to maintain itself as one of fixity; and therein I think we would find a difference between the paranoidal form of dementia præcox and true paranoia. The paranoiac must have strength to cling to a belief, especially if it be surrounded with systematized delusions that give it an air of possibility. I would like Dr. Dercum's opinion as to whether it is not true that one of the distinctive features of difference between dementia præcox and paranoia would be the existence of true dementia in the former and only of a pseudo-dementia in the latter; and whether also it is not true that in those hebephrenic forms which have such a comparatively favorable prognosis as to recovery, there is not foreshadowed and threatened the same terminal dementia that characterizes cases which do not recover, or which because of the removal of the toxic or other agencies which tend to the perpetuation of the condition, simply escape before this change has taken place.

Dr. Albert E. Sterne, Indianapolis: We should take out of the group of dementias what does not belong there; we should reserve our conception of dementia for that which goes hand in hand with an organic decay, an actually destructive lesion of the brain cell, a practically incurable condition—a true dementia. Dr. Dercum mentions the quantitative loss, but means no doubt to include the qualitative loss also in mental acuity. I have frequently been deeply impressed with this feature of the prognostic aspect of the various insanities. It has seemed to me that most physicians are not sufficiently ready to regard those mentally ill as sick people. This is especially true, it seems to me, of the acuter conditions. I have through a long term of years come to the belief that mental conditions do not rise out of the surrounding ether, but have a distinct basis; that these patients are sick. I have never been, in meeting mental conditions, more deeply impressed with the truth of this than in those cases to which Dr. Dercum refers, namely the confusional type, especially in the hebephrenic class. It has been my invariable custom to treat these patients as seriously sick and to keep them in bed. Temperature and heart action should be carefully watched. I have been surprised innumerable times to find a rise in temperature sometimes up to 102, possibly a little higher—with a disturbance of the heart action—a marked irregularity in several cases. I have been imbued with the feeling that these cases are of cerebral character—a true inflammation of the cerebral tissue. I have not been able to believe that we are dealing merely with toxic conditions because the heart action does not simulate that which we see in those cases which we term toxic insanities ordinarily. The prognosis in these confusional cases is not so bad. I agree with Dr. Dercum that the relative number of recoveries in this class of cases is much higher than is commonly believed; and I believe it is the fault of the treatment rather than the condition itself which makes the number of recoveries low. By this I mean that we are inclined to neglect the truly serious physical aspect of such cases on account of the prominence of those symptoms commonly designated as mental.

Dr. F. X. Dercum: It is easy to differentiate between dementia præcox and simple dementia. In an ordinary case of senile dementia, among the early symptoms are failure of memory, of orientation, and gradually the faculties generally. Preservation of memory, even in cases which become finally demented, and full preservation of orientation exist in dementia præcox. The term *démence précoce* is unfortunate and has given rise to an unfortunate mental attitude with regard to these cases. Dementia præcox occurs in a very large number of cases in persons who are neuropathic—who are organically and structurally defective. There are in them some disturbances of development, arrests or deviations involving the organism as a whole, the nervous system, bones and muscles, cardiovascular apparatus, and no doubt also the ductless glands. When puberty is reached and the organism is obliged to adapt itself to new conditions, it can not meet the demands made on it; the patients become toxic, suffer from a toxic metabolism and present the mental symptoms of toxic confusion. A case of organic dementia certainly presents a very different picture from dementia præcox. Hebephrenia, catatonia, paranoid dementia, paranoia hallucinatoria and paranoia simplex are all closely related. They form a natural series. As practical physicians we ought to remember that many of the patients, though they are defectives, are suffering in addition from exhaustion and that frequently they can be improved and at times even cured by rest and hypernutrition, methods that are beginning to be used more and more.

EPIDEMIC INFANTILE PARALYSIS.*

M. ALLEN STARR, M.D., LL.D., Sc.D.
Professor of Neurology, Columbia University.
NEW YORK.

During the summer of 1907 an epidemic of infantile paralysis occurred in New York City and its vicinity. The number of cases (probably over 2,000) was so many, the extent of the disease in the city and along Long Island Sound into Connecticut and up the Hudson River as far as Ossining was so rapid, the severity of the cases was so intense and deaths from the disease so frequent, that the epidemic excited a great amount of interest both among the laity and the profession. It seems wise, therefore, to put on record some special account of this epidemic, to call attention to particular clinical features that were presented, to trace the course of the cases as far as possible, and also to bring together an account of other epidemics that have occurred in the past, inasmuch as a large number of records have now accumulated concerning the prevalence of this disease in epidemic form.

Through the kindness of Dr. Simon Flexner I am enabled to present the results of a biological study, made by Dr. Martha Wollstein at the Rockefeller Institute, of the cerebrospinal fluid from cases of the disease, and also the results of an autopsy on one case.

THE COURSE OF THE EPIDEMIC IN NEW YORK.

The epidemic of poliomyelitis occurring in the city of New York in 1907 began about May. The number of cases increased steadily during June and July, the height of the epidemic occurring in August and September. Cases continued to appear in October, and a few were reported in December. The epidemic was widespread, cases occurring not only in the city of New York, but also in Brooklyn, Long Island City and the Bronx. Some cases were also reported on Staten Island, and many cases were seen along the Hudson River as high as Ossining, which is fifty miles from New York. Cases were also reported along the sound at Mount Vernon, Stamford and Norwalk (forty miles from New York), and in some of the valleys of Connecticut within twenty miles of the sound. Cases were not observed in New Jersey or in the suburbs of Newark. It is estimated that nearly 2,000 cases of the disease occurred during this epidemic, and the mortality was probably 6 per cent. to 7 per cent.

The summer, though a hot one, was not unusually so; but it was unusually dry, the reports of the weather bureau showing that the rainfall was 1.18 inches in July and 2.48 inches in August, less than half that of previous years. Other infectious diseases were not particularly prevalent.

In but few of the cases of infantile paralysis recorded had there been any preceding infectious disease.

The onset of the disease was uniformly accompanied by a brisk febrile movement, temperature rising to 101 to 103 in the first twenty-four hours: sometimes by a slight chill (but this was the exception); usually by vomiting, malaise, general sweating, general severe pains in the limbs and in the back, sometimes attended by some rigidity of the spine and even in some cases by retraction of the head giving rise to the suspicion of a beginning meningitis. The excessive sweating which attended the fever has been observed in other epidemics, and is interesting in view of the fact that it implies an involvement of the vasomotor centers in the gray matter of the cord. Diarrhea frequently followed on the second day and continued for two or three days. Delirium was a common accompaniment of the fever on the second or third day. The febrile movement lasted from five to nine days in the majority of the cases. It was rarely attended by very high temperature, and even in the fatal cases temperatures above 104 were the exception. On the third or fourth day of the disease the paralysis was discovered. It may have developed a little earlier, perhaps on the second day in some of the cases, but the children were confined to bed; they were usually extremely tender to touch and showed such pain on movement that they were allowed to lie quiet, and hence the paralysis very often escaped notice until the third or fourth day. It usually appeared with considerable suddenness and at its maximum extent from the beginning. It remained as the chief symptom after the fever had subsided and after the pains had become less. In the vast majority of the cases the legs were chiefly affected. In some of the cases the disease affected the arms as well; in some cases the muscles of the back and even of the abdomen were affected. In a few cases paralysis extended to the neck and to the face, and in a few cases the eye muscles were also involved. The picture was, therefore, in some cases that of poliomyelitis of the ordinary recognized type; in other cases, of poliomyelitis with bulbar paralysis; in other cases, of poliomyelitis with polioencephalitis of Wernicke. In a few cases it was noticed that the children were affected by true infantile hemiplegia; and this disease appears to have been more common during last summer than usual, although by no means occurring in such frequency as poliomyelitis. The increased frequency, however, of the disease leads to the natural supposition that the infectious agent in some cases involved the motor nuclei of the lower segment, the spinal cord, the medulla, pons, and crus, and in other cases involved the motor nuclei of the cortex, producing the infantile hemiplegia or encephalitis of Strumpell.

In the cases of poliomyelitis where the legs were affected it was not at all uncommon to have retention of urine and loss of control of the bladder extending through several days, but in no case has a permanent loss of control been found. In many cases where the arms were affected the respiratory muscles were also involved, and in fatal cases death occurred from respiratory paralysis or from heart failure rather than from any febrile affection. When the face was affected a typical Bell's palsy was usually present with inability to close the eye and with a reaction of degeneration in the facial muscles. In the cases where the eyes were affected strabismus, either internal or external was observed, but this, as a rule, was temporary and in no cases that I have seen has a permanent strabismus remained. The paralysis was always of the flaccid type with rapidly following atrophy in the muscles and a rapid loss of faradic reaction.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

The pain, which was a very marked symptom in almost all the cases, was referred to the muscles or to the back; was greater in the part that was paralyzed, though usually felt all over the body; and in some of the cases was attended by a hypersensitiveness to heat and cold, or to one or the other. Pain is a usual symptom in anterior poliomyelitis. It is undoubtedly due to the intense congestion of the gray matter of the spinal cord through which the pain and temperature tracts pass. Anesthesias were not observed. The limbs, however, soon became cyanotic and cold and remained so. In many cases an extreme hypersensitiveness to pain, especially the pain of the electrical current, was noticed, and in many cases this persisted.

The acute onset usually subsided in the course of a week or ten days and a state of improvement was noticed beginning at the end of the second to the fourth week. This improvement in a vast majority of cases has continued up to the present time, and as a rule such improvement is likely to go on for two years.

It has also been noticed that in many cases a complete recovery has ensued. In these cases the paralysis was never very intense but still was marked; in other cases it amounted merely to a sense of great fatigue and unwillingness to use the muscles for a week or ten days, followed by entire recovery. The frequency with which such cases, which might be termed "abortive cases," was observed is rather unusual, though in other epidemics the same type of cases has been noticed. On the other hand very rapidly fatal cases were observed, and, although the mortality is somewhat indefinite, it may be stated that it amounted in this epidemic to about 7 per cent. As death is a very rare occurrence in sporadic cases, the mortality in this epidemic is remarkable.

A number of these cases were very carefully studied by Dr. Martha Wollstein in the Rockefeller Institute for Medical Research under the direction of Dr. Simon Flexner. Through their courtesy I am enabled to present their results, which will be more fully published by them later. The following statement has been prepared by Dr. Wollstein.

A BIOLOGIC STUDY OF THE CEREBROSPINAL FLUID IN ANTERIOR POLIOMYELITIS.[1]

Twenty cases were studied in children ranging from 5 months to 8 years of age; nine were over 2 years, and four were under one year. Cerebrospinal fluid was obtained by lumbar puncture from the second day to the eighth week of the disease, as follows:

2nd day, 1 case. 7th day, 2 cases. 3rd week, 6 cases.
4th day, 2 cases. 10th day, 2 cases. 4th week, 1 case.
5th day, 1 case. 11th day, 1 case. 5th week, 1 case.
6th day, 1 case. 12th day, 1 case. 6th and 8th week (same case) 1 case.

The fluid was always clear and colorless, unless mixed with blood. Smears prepared at once, after centrifugalizing five to thirty minutes, and after twenty-four hours' incubation, were stained with methylene-blue and with Gram's method. In fourteen cases cellular elements were entirely absent; in six cases a few mononuclear leucocytes were found. Large numbers of leucocytes were never present.

Cultures were made in plain agar, ascitic-agar, and blood-agar, and in plain and ascitic bouillon.' They were incubated both aerobically and anaerobically. In fifteen cases the fluid was sterile by both methods. In one a white staphylococcus grew; in one a Gram positive bacillus and in three a large, Gram positive coccus appeared in tetrads and pairs within large groups. It grew abundantly on all ordinary culture media, and was apparently similar to the coccus described by Geirsvold. The fluids from which the coccus was cultivated in my cases were withdrawn on the fifth day, sixth day and in the fifth week after the onset. In two cases it was present in one specimen of fluid only, subsequent punctures withdrawing sterile fluid. In the third case the coccus was cultivated from a second specimen obtained three days after the first, or on the eighth day of the disease; two later fluids from the same patient proved to be sterile.

The coccus was looked on as a contamination.

An autopsy was obtained in one case only. It was that of a boy 2½ years old who died of tubercular meningitis two months after the onset of his poliomyelitis. An area of softening was found in the lumbar region of the spinal cord, 3 cm. long and affecting only the right anterior horn. There was also a general miliary tuberculosis involving the cerebrospinal meninges, pleura, lungs, spleen, liver, lymph nodes and intestines. Microscopic examination of the cord lesion showed that it was in the subacute stage and limited to the anterior horn.

The spinal cord, medulla, sciatic nerves, tibial muscles, and all the internal viscera were ground up, dried, and extracted (Levaditi and Marie's method) to be used in the complement deviation tests.

Blood was obtained from the median basilic vein in seven cases, 5 to 10 c.c. being withdrawn. Blood cultures in two acute early cases were negative.

Complement binding experiments were made in four different ways:

1. Cerebrospinal fluid from the most recent case (second day) was tested against the blood serum of cases suffering from the disease for five days, three weeks and eight weeks respectively. No binding of complement resulted; hemolysis complete.
2. Same fluid with the fluid from a late case, eighth week. Results the same.
3. Serum against cerebrospinal fluid from the same case, as well as against the fluid from more early and more recent cases. No binding of complement; hemolysis.
4. Extracts of spinal cord, medulla, sciatic nerves, tibial muscles and liver were tested with the serum from cases of poliomyelitis in the eighth week, third week and on the tenth day after the onset. No binding of complement; hemolysis complete. Controls were made with normal organ extracts and normal serum with identical results.

It was unfortunate that no uncomplicated autopsy could be obtained; but the results of the tests show that the diagnosis of poliomyelitis by means of a serum reaction is apparently not possible. No light is thrown on the etiology of the disease by this means.

THE BACTERIOLOGY OF THE DISEASE.

The question of the bacterial origin of this inflammatory process has excited the greatest interest during the past few years. Authorities are not as yet agreed on this question. A number of years ago Schultze described a case of anterior poliomyelitis in which he had found a diplococcus in the cerebrospinal fluid, and in isolated cases here and there through literature confirmation of this finding has been recorded. In the epidemic in Norway reported by Geirsvold a diplococcus was observed in a number of the cases. Harbitz and Scheel[3] described carefully the pathology of seventeen cases examined in this epidemic. They described the infiltration of the spinal pia with lymphocytes more marked on the anterior surface of the cord and following the sheath of the central arteries and veins. They describe a very marked condition of hyperemia, edema and exudation within the spinal cord and a marked cell infiltration in the gray matter of the anterior horns. They describe the infiltration of the vessel walls in the white substance with lymphocytes and a typical degeneration of the ganglion cells, but only in a few cases was there any evidence of the presence of micrococci. These were of the nature of diplococci, but were not uniformly found. In the careful autopsies made by Wickman in the Swedish epidemic the same conditions were observed and here again there was an absence of any uniform finding of bacteria. In eight autopsies careful cultures were taken; in four the result was negative. in one *Staphylococcus albus* was found, and in the three others *S. aureus* was discovered. These were considered as accidental infections of the test-tubes and not as causative agents of the disease. In the cases examined in the Rockefeller Institute in the epidemic in New York bacterial investigation was also negative.

---

[1] From the Rockefeller Institute for Medical Research, New York.

While, therefore, the clinical history of the disease implies an infection, it must be admitted that up to the present time the organism responsible for the disease has not yet been discovered and that it is still a matter of uncertainty whether the causative agent is a micrococcus or is a toxin. The weight of evidence is, however, in favor of the latter hypothesis.

EPIDEMICS OF INFANTILE PARALYSIS.

A careful search through literature has shown that epidemics of infantile paralysis are more common than has been supposed. It has been possible for me to collect from original sources accounts of forty-four such epidemics, and as these have not hitherto been collated they are presented here in the order of their occurrence:

Colmer[4] saw a case of infantile hemiplegia in West Feliciana, Louisiana, in the fall of 1841 and was informed that ten other cases of infantile hemiplegia or paraplegia had occurred during the preceding three or four months within a few miles of the residence of the patient whom he saw. All the patients were under two years of age and all had recovered completely, or were improving.

In view of the accounts of subsequent epidemics here gathered, there seems to be no doubt that this was a true epidemic of infantile paralysis. Complete details are not to be found.

Bergenholtz[5] first reported an epidemic which occurred in 1881 in the town of Umea, North Sweden. Thirteen cases were observed, but a full account was never published.

Cordier himself[6] observed in June and July, 1885, in the town of Saint Foy, near Lyons, France, thirteen cases in a town whose population was fifteen hundred. Other cases were recorded and heard of in the same locality. These cases all occurred within the months of June and July; and of the thirteen cases, four died within four days of the onset, of respiratory paralysis. In all cases the onset was accompanied by fever, by severe pains and marked sweating. The incubation period was thought to be between ten and thirty-six hours. Almost all of the patients were infants under the age of 3, the youngest being 3 months old, several of them 6 or 7 months old. One man of 27, the brother of a little girl of 9, was the only adult affected. As the majority of the patients were nursing babies, it was thought that food could not have been the source of the infection. It was noticed that retention of urine occurred in one case. In ten of the cases the legs were affected, and in six cases one or both arms.

Oxholm[7] reported an epidemic in Mandel, Norway, in July, August and September, 1886. Nine cases were recorded without any deaths. The children were between six months and four years of age, and the onset was accompanied with fever in all cases.

Medin[8] observed an epidemic in Stockholm between the months of May and November, 1887. Forty-three cases were reported, in which there were three deaths. In many cases it was noticed that there was retention of urine from one to three days at the onset of the disease. Convulsions occurred in two cases. Bulbar symptoms occurred in nine cases; facial paralysis in three cases alone, and in five cases, in connection with paralysis of the limbs. In one case the muscles of the eyes were involved, and in one case a condition of hemiplegia corresponding to the polioencephalitis of Strumpell was observed. It was noticed in this epidemic that several cases occurred in one house, a brother and sister being affected together in one or two instances. Medin, who made this the subject of an important address at the Tenth International Medical Congress in 1890, was the first to call particular attention to the epidemic occurrences of infantile paralysis.

Putnam[9] observed in the summer of 1893 an unusual prevalence of cases of infantile paralysis appearing in the dispensaries of Boston. This can hardly be called an epidemic, for the patients came into Boston from several towns in the vicinity and the disease did not appear to be exceptionally prevalent in the city of Boston; but Putnam called attention to the fact that while in four of the dispensaries in the previous year the average number of patients was six or eight, in the year 1893 twenty-six cases were observed in the months of August and September. In none of the cases that he saw did a fatal result ensue, but all the children were left with some permanent paralysis.

André[10] saw four out of nine cases of infantile paralysis observed at Saint Girons, near Toulouse, in France, and in its two adjacent towns, Cescau and Seix, in July and August, 1893. These all occurred in infants under the age of 3 years, with fever and general symptoms of infection. A brother and sister were first taken, then two children in a house very near to them, then other isolated cases. Two out of the 9 cases presented cerebral symptoms. They all recovered.

Caverly[11] reported the first serious epidemic in this country, which occurred in Rutland, Vt., between July and September, 1894. Rutland lies in a valley; and it is interesting to note that in a large number of these epidemics the site of the occurrence has been near a stream in a narrow valley during a summer which has been extremely hot and rather dry, when the brooks run low and the stream is below its ordinary limits. This was the case in Rutland. Caverly records 126 cases, with eighteen deaths; 85 patients were under the age of 6, 21 between 6 and 14, and 13 over the age of 14, so far as the ages were recorded. In the majority of instances the disease began with a febrile onset; pain was noticed in many, so that for a time it was supposed that the disease might be a mild type of cerebrospinal meningitis. Convulsions occurred in many cases; in quite a number there was retention of urine; in two there were bulbar symptoms; in one, the face was paralyzed and in one some of the muscles of the eye. In the course of this epidemic it was noticed that a good many individuals were affected with an acute febrile onset, great prostration and much fatigue, where the disease did not go on to a true or permanent paralysis, and in a great many cases an entire recovery occurred. The legs were affected to a very much greater extent than the arms. It was noticed that in this epidemic animals—horses, dogs and chickens—were also affected.

Pieraccini[12] observed a small epidemic in Monte Spertoli, a small village not far from Florence, Italy, lying on the side of a mountain in quite a high altitude and a dry locality. This epidemic occurred between June 23 and August 10, 1895. There were but 7 cases, all the patients being under the age of 5. In 6 of the cases the legs were affected, in one case an arm, and in one patient internal strabismus was noticed. These patients all recovered.

Buccelli[13] saw a number of cases in the Ravecca quarter of Genoa in 1895. Other quarters of the city did not present similar cases. Two occurred in one house; two others were brothers; and during this epidemic it was noticed that several cases of cerebral palsy occurred at the same time, two of them in the same house with a case of spinal paralysis. These cases were not particularly severe. The legs were affected in the majority of instances. They all occurred with febrile movement. Buccelli adds that at the same time an epidemic prevailed in Arenzano, a small suburb of Genoa. Five cases were observed within a few days by Dr. Luciani.

Medin[14] observed an epidemic in Stockholm in the summer of 1895, which he reported with great care. There were 20 cases observed between the months of June and September. Three of these cases presented facial palsy and five of them bulbar symptoms. In all of them the onset was accompanied by fever, and in the majority the paralysis affected the legs. There were no cases of infantile hemiplegia noticed at this time, and no deaths. Medin believed that there was a specific poison causing the infection and that in several cases it was probable that the direct contagion could be traced from one patient to another. This epidemic occurred in the latter part of the summer and early fall, at a time when infantile diarrhea was quite prevalent in Stockholm.' The onset in the majority of cases was sudden, with fever and somnolence, but sweating was not specially noticed. Vomiting and diarrhea were common, and, in many cases, retention of urine. Pain and sensitiveness of the body were noted in very many cases. In two cases Medin considered the condition as probably polyneuritis rather than poliomyelitis, there being first pain, then hyperesthesia of the skin, followed by anesthesia of the legs. In five cases there was an acute ataxia which he also ascribed to peripheral neuritis. The fact that in both this epidemic and that which he observed in 1887, polioencephalitis acuta was observed in a number of cases led Medin to the conclusion that this disease was produced by the same infection as poliomyelitis, the only difference being in the location of the portion of the nervous system affected.

Altman[15] observed an epidemic of eighteen cases at Port Lincoln, South Australia, during the months of March and April, 1896, the hot and dry months in Australia. This appears to be the first epidemic on record in Australia. Port Lincoln is a small town having a population of fifteen hundred. The patients were all over the age of 3 years. In two instances two members of the same family were affected. The symptoms began with fever and pain and the paralysis developed on the third or fourth day in all the cases. In one case there was retention of urine, in one case facial palsy; and one case was hemiplegic in its type. None of the patients died.

Pasteur[16] observed at Much Hadham, in England, in the month of July, 1896, seven cases of infantile paralysis in one family living in the same house, all attacked within ten days. The neighborhood was a healthy one and there were no particular circumstances indicating in any way the cause of the disease. The children ranged in age from 1½ to 11 years. The first child had a paralysis of the left arm, the second had typical right hemiplegia, which was undoubtedly cerebral in nature, as the electrical reactions remained normal. The third and the fourth had fever for several days and general weakness, but had no paralysis. The fifth child had a typical spinal palsy of the left leg, the sixth had a febrile onset with general tremors and great prostration, with no paralysis, and the seventh child had a fever with a temporary internal strabismus. It would seem probable that in this family some poisonous agent had infected all the children who responded in different manners to the infection. There were no other cases observed in the neighborhood.

Taylor[17] saw in July and August, 1896, seven cases of infantile paralysis in Cherryfield, Me. This appeared to be infectious, as the second patient was a brother of the first, the third a cousin of the first and second, and the fourth was visiting in the house where the first three patients were affected. In all these four cases both legs were paralyzed and in three of them one arm was also affected. The fifth case was a little girl of 10 who died on the seventh day of the disease, the paralysis having ascended from the legs to the arms and affected the respiratory muscles. Two other cases were known to have occurred in the same town, but were not seen by Dr. Taylor. He also heard of two cases occurring at the same time in a neighboring town.

Bondurant[18] reports fifteen cases occurring in Greene County, Ala., during the summer of 1896, both whites and negroes being affected. There were no deaths. Malaria was prevalent at the time.

Buzzard[19] called attention to the fact that an unusual number of cases of infantile palsy were observed in a small district of London in September, 1897, and gives the details of eleven cases. Some of these developed subsequently to influenza. They were all children under 5, excepting one boy of 14. In two instances the patients were sisters, or a brother and sister. In one case there was retention of urine. In the majority of instances the legs were affected. In two of the patients the febrile onset was attended by great weakness, but rapid and complete recovery ensued. There were no deaths. Several other cases in addition to these eleven were heard of but not seen at the time.

Taylor[20] saw a rather unusual number of cases of infantile palsy at the Hospital for Ruptured and Crippled during July, 1897, and was under the impression that there might be an epidemic of the disease, though no other records of such an epidemic are to be found. The cases were widespread through the city of New York, and it is not certain that all had developed during the month of July, though it is quite unusual that twelve cases should appear at one hospital in one month, in this city. He does not record this as an epidemic, but in a letter to the *New York Medical Journal* inquires whether it might be the beginning of an epidemic.

Pleuss[21] records four cases which had been observed between June and September in Kiel. It does not appear, however, that this can be entitled to consideration as an epidemic, since the population of the city is so great. These cases might easily be accounted for as sporadic cases.

Newmark[22] of San Francisco records a small epidemic occurring in the town of Le Grand, Merced County, Cal., in June, 1898. It is a village of forty-nine people. Four children were affected, the first and second being brothers, the third a playmate of the first and second, and the son of the doctor who attended them. They were all boys from 8 to 10 years of age. The onset was with fever and the legs were paralyzed in all the cases. In one there was retention of urine for a week. None of the patients died.

Packard[23] records the fact that during the summer at Royersford, Pa., he had seen two cases of infantile paralysis developing in the same house within three days of each other in a brother and sister. This fact he considers of importance as supporting the infectious origin of the disease and also its possible contagion.

Auerbach[24] records a small epidemic occurring in Frankfort on-the-Main between May and December, 1898. There were nine

cases observed by him and several others were heard of. Two of these cases occurred in the same street. In one case facial palsy accompanied the paralysis of the arm and leg, but was of the peripheral type. In one case there was a recurrence of the disease in August after the first attack in June, a case which is worthy of notice as it is the only one that I can find on record of the occurrence in the same individual of two attacks.

Zappert[25] describes an epidemic which occurred in Vienna in 1898. Two hundred and eight cases were observed during that year and these cases occurred chiefly in the summer between June and November. Infants under three were attacked and no cases were observed in which children in the same family were attacked. There was no relation to other infectious diseases.

Wickman[26] observed fifty four cases during an extensive epidemic in Stockholm in the summer of 1899. Three patients died. The disease was attended by febrile onset and presented all of the characteristics of the epidemic type as seen in other epidemics. In three different houses two cases of the disease occurred, and in several families two or three cases were observed among cousins or brothers and sisters. The majority of the cases occurred in July, August and September, and almost all of the patients were below the age of 5. Wickman noticed that the disease was not generally spread through the city, but was particularly localized in certain parts, so that in neighboring houses in the same or in neighboring streets, groups of cases of three, five or seven were observed. In one instance there occurred a case in one dwelling house from which the family removed on October 1. A second case developed in this same house in the family that moved into the rooms which had been vacated by the first family not long after their entrance. He considers this as a pretty good proof of the contagiousness of the infection, of which he saw many other examples in the epidemic of 1906.

Leegaard[27] observed in Bratsberg, Norway, between April and November, 1899, fifty four cases of the disease. Thirteen occurred in August, September and October. All ages were affected, but the majority were children under 11. Two patients died. The disease had the typical febrile onset, the lower extremities were affected in more cases than the upper, in one case there was facial palsy and in one case the tongue was paralyzed.

Chapin,[28] who was called to see some cases in consultation during an epidemic in Poughkeepsie, N. Y., in July and August, 1899, gives the details of seven cases, with one death. Thirty or forty cases were observed by the physicians there during the summer. The majority of the cases went on to complete recovery, a fact which has been noticed in a number of the different epidemics and has a bearing on the prognosis. Some were left with permanent paralysis. In the case of the patient who died an autopsy was performed and a diplococcus was found by cultures of the spinal cord.

McKenzie[29] describes seventeen cases occurring in the small towns of Washington and Amenia during the summer and autumn of 1899. These towns lie about ten miles east of Poughkeepsie and the epidemic there coincided with the one described by Chapin. Persons of all ages were affected in this epidemic from infants of 2 to adults of 35. Of the seventeen cases three died within four days of the onset, one recovered entirely after four weeks' illness; in one case retention of urine was observed. Two of these cases presented symptoms quite similar to those of Landry's paralysis and were so described.

Painter[30] saw fifty two cases of infantile paralysis between the months of June and September, 1900, in Gloucester, Mass.; thirty eight of these cases were under his own care. They were in children between the ages of 13 months and 10 years, and presented all types of infantile paralysis. There were, however, no deaths. In a number of cases it appeared as if contagion was possible, two members of the same family being affected.

A. M. Woods[31] witnessed an epidemic in San Francisco in May and June, 1901. The weather was damp and cool. Fifty-five cases were recorded, of which twenty five were reported in detail. The majority of the cases occurred in infants. The onset was attended with fever and the paralysis affected the legs in many cases. There were no deaths.

Wickman[32] observed twenty cases in Gotteborg, Sweden, between the months of July and November, 1903. Eleven of these were under 2 years of age, five between 3 and 5 years of age, the remainder older. Three were sisters. In one instance there were two cases in the same house. One patient died. The usual history of febrile onset was observed in all the cases, and in all some slight degree of permanent paralysis was left.

A. Lorenzelli[33] saw twenty-six cases in Parma, Italy, between the months of March and September, 1903, chiefly in infants under the age of five. The disease began with fever and was not fatal in any case, but permanent paralysis was left in the majority of the cases.

Blackhall[34] observed six cases at Queanbergan, New South Wales, during an extensive epidemic of poliomyelitis in the months of December, 1903, and January and February, 1904, which is the hot season in New South Wales. Two of these patients were sisters, two were cousins, and one case occurred in the house next to the one in which the sisters were affected. They were all typical cases of infantile palsy. In one case there was a facial paralysis. None of the cases was fatal. Various epidemics in different places at some distance from one another were recorded by different authors.

Litchfield observed twenty-five cases at Sydney. He notes that the summer was rather wetter and cooler than usual and that during the summer there was an extensive epidemic of gastrointestinal influenza. The patients affected were all under the age of 6. There was an onset with fever and general malaise with sweating in one-half of the cases. In the other cases the disease appeared to come on with some prostration, but without much fever. All the extremities were affected in one case; two legs, in ten cases; one leg, in ten cases; one arm in four cases. There were no fatal cases. Lumbar puncture was not performed in any of the cases recorded by him.

R. B. Wade observed thirty-four cases at Stanmore, near Sydney, the patients being all below the age of 7 years. In almost all of these cases there was a febrile onset with vomiting, diarrhea and severe sweating. The temperature was between 99 and 100 for two or three days, then rose on the third or fourth day to 102, with an increase of the pain and the appearance of the paralysis. Paralysis appeared from the first to the sixth day. There was retention of urine in seven of the cases. None of the cases was fatal. In some of the cases there was complete recovery in two or three weeks; in the majority, however, some permanent paralysis was left. In several cases two or three members of a family were affected. Sometimes one member would develop paralysis and the others after several days of general malaise and undue fatigue would recover without paralysis. The legs were affected much more frequently than the arm. In one case the body muscles were involved, in one case the abdominal muscles, and in one case the face. This is the second epidemic known to have occurred in Australia.

B. B. Ham[35] saw a severe epidemic in Brisbane, Queensland, from October to December, 1904. One hundred and eight cases being reported, almost all of the patients being under the age of 10. Four of the cases were fatal. The course was febrile, the paralysis was limited to the extremities, there being no facial or bulbar paralysis. Cerebrospinal meningitis was prevalent at the time. No lumbar punctures were made. This was the third Australian epidemic.

Nannestad[36] observed forty-one cases of the disease in Hvalen, Norway, in the summer of 1904, between June and October. The majority of the patients in these cases were infants, but some were adults. The epidemic was light, the degree of paralysis not extreme, and no patients died.

PLATON[37] observed, in the same year and in another part of Norway, a small epidemic at Aafjorden, in the month of August. There were twenty cases and of these six died. A number of these cases appeared to prove the contagiousness of the disease.

GEIRSVOLD,[38] in Norway, reported the most extensive epidemic hitherto recorded, which occurred in Norway and Sweden in the summer of 1905. Geirsvold made a careful study of this epidemic in Norway and observed 437 cases around the neighborhood of Trondhjem, between April and October; there were sixty-seven deaths. In a number of cases it appeared as if the disease were manifestly contagious, and Geirsvold was able to trace the extent of the disease by contact from one village to another and from one house to another. It is, however, to be remarked that in a general discussion about the epidemic among the Norway physicians,[39] opinions differ as to the contagiousness of the affection. Some physicians laid particular stress on the condition of the water supply in various localities and pointed out that the disease was more prevalent in damp places surrounded by swamps. In this epidemic lumbar punctures were made by Geirsvold in eleven cases. From the fluid obtained through lumbar punctures micro-organisms were found many times. These were bean-shaped diplococci or tetracocci with flat sides toward each other, often seen in chains of four to six members. This diplococcus grew well in ordinary serum, and stained with aniline dyes. A particular feature of its character was the clear dividing line between the two half-balls which lay parallel to the axis of the chain. The same microbe was found in the pharynx of a patient suffering from poliomyelitis. Cultures from this micro-organism injected subcutaneously into mice, rabbits and dogs uniformly produced paralysis of their hind legs. This micro-organism was identified by Dethloff as the same organism found by him and Looft in 1901 in two cases of poliomyelitis and as the same micro-organism described by Huebner as occurring in a case of poliomyelitis under his observation.

WICKMAN,[40] in a remarkably careful study described in detail 1,031 cases occurring between the months of May and October, 1905, in the southern part of Sweden. These cases were distributed through a large number of small villages adjacent to one another, and Wickman believes that the records, which he has investigated with great care, prove conclusively the contagious character of the infection. Many cases occurred in the same house; in many instances two or more members of the same family were affected. In one town it was evident that sixteen or eighteen cases originated from the same schoolhouse. In the majority of instances some contact could be traced between one patient and another, and even the spread from one village to another could be accounted for by the passage of individuals from one town to the next town. The period of incubation appeared to be between one and four days. The poison remained in the house, so that new tenants were very often affected by the disease after old tenants had removed. In two cases an interval of one year's duration occurred between two cases in the same house. The care with which Wickman investigated the question of contagion and the mode of extension of the disease has not been equaled in the study of any other epidemic; and from his evidence it is very hard to escape the conclusion that the disease is actually contagious or that, like scarlet fever, it can be carried through the medium of another person to other individuals. Wickman calls attention to a large number of varieties in the disease. He speaks of the abortive type, in which individuals were ill for three or four days with febrile movement, followed by a condition of considerable prostration, and then a recovery with no paralysis remaining. Such cases have been recorded in many of the other epidemics, and therefore the conclusion may be accepted that there are light cases of the disease not recognized as paralysis because true paralysis does not ensue. He also calls attention to a type in which symptoms indicate the existence of polyneuritis accompanying the poliomyelitis. There is no question that the two diseases may occur together in sporadic cases of infantile paralysis; and in the other epidemics isolated cases have been reported in which the pain, the tenderness along the muscles, the hypersensitiveness of the skin, all indicate the possibility of an involvement of the peripheral nerves. It is therefore probable that this type of the disease should be recognized. The existence of bulbar symptoms, and particularly of cranial nerve symptoms, in a number of the cases is insisted on by Wickman, but these have been observed as already stated in many of the previous epidemics. It may be mentioned that in Sweden dogs and other animals were apparently affected with this disease at the same time as children. It will be recollected that Caverly called attention to this fact in connection with the epidemic in Vermont.

Lumbar puncture was performed in a number of the cases observed by Wickman and cultures made of the spinal fluid, but no trace of the diplococci described by other authors was found, and even in the cases that came to autopsy cultures of the spinal cord failed to reveal any micro-organisms. Wickman therefore places a certain amount of doubt on the observations of Geirsvold already described.

WICKMAN[41] saw a smaller epidemic in Sweden in 1906, only fifty cases being observed. They presented the same features noticed in the larger epidemic.

LUNDGREN[42] observed an epidemic of anterior poliomyelitis at Vardo in Norway in the summer of 1905. He records 403 cases, occurring chiefly between the ages of 6 and 15, though some adults were also affected. This disease apparently was contagious, as many cases were traced where the contagion seems evident. He thinks the time of incubation is from eight to ten days. This epidemic was a very fatal one, for 10 per cent. of the patients died. Many recovered, but permanent paralysis of some type was left in 25 per cent. of the cases.

TERRIBERRY,[43] who first called attention to the extensive epidemic occurring in New York in the summer of 1907, heard of a small epidemic at Ridgway, Pa., which occurred during July, August and September, 1907; and he visited the town in order to investigate this epidemic. He found Ridgway situated in a valley in the Allegheny Mountains about sixteen miles in length. Fifty cases developed in this little valley, the first case appearing at Elk Creek, where twelve cases were observed. Two weeks later cases appeared at Ridgway, nine miles below Elk Creek, and in that town thirty cases eventually occurred. One week after the case appeared in Ridgway, cases developed at Portland Mills, nine miles below Ridgway, and there eight cases in all developed. It was evident, therefore, that the disease extended down this valley in a definite direction, and that the incubation was in some cases one week, in others two.

Of the fifty patients four died. The patients were all children and in every instance two or three members of the same family were attacked by the disease. He mentions that in three cases bulbar symptoms developed.[44]

GRIFFIN[45] reports an epidemic occurring in Oceana County, Michigan, in the summer of 1907. There were twenty cases, chiefly in infants; the limbs were paralyzed in all cases. In one case the face was involved.

S. M. FREE[46] reported an epidemic observed at Dubois, Pa., in the summer of 1907. Over one hundred cases were observed in the Allegheny Mountains about Dubois. There were only a few deaths. The disease presented some meningeal symptoms and much pain and the paralysis involved the legs, chiefly. Pigs and chickens also were affected.

[44] Several authors in collecting the accounts of epidemics have included in their lists references to Briegleb, Inaugural Dissertation, Jena, 1890. The cases reported by Briegleb, however, were single cases developing in places far apart and could by no means be regarded as an epidemic. One author has mentioned Cervesato as having reported an epidemic in Padua in 1897. The article of Cervesato, Corriere de Milano, 1897, viii, No. 1, is an analysis of twenty-six cases of the disease, and calls attention to pain as the initial symptom in poliomyelitis, but is in no sense a record of an epidemic.

PROGNOSIS.

Some interesting facts in regard to prognosis have been elicited in connection with these recent epidemics. Ordinarily the mortality of anterior poliomyelitis in sporadic cases is very low, but it will be remembered that in the epidemic types the mortality has varied from 6 to 10 per cent., which makes the disease an alarming one. It has been noticed that in the fatal cases death occurred as a rule between the fourth and tenth days, the majority of fatal cases terminating on the sixth day from the extension of the paralysis to the respiratory muscles. High fever was not often noted and there was no evidence, as a rule, of heart failure, but the paralysis extended upward, involving the respiratory muscles of the throat, and patients died of respiratory palsy. The prognosis, therefore, is always serious while the disease is advancing or while the paralysis is extending, especially as it extends upward. If a child survives the eighth or tenth day, prognosis for life is favorable.

On the other hand, epidemics have demonstrated the fact that in 25 per cent. of the cases there is complete recovery. Such complete recoveries are not often observed in the sporadic cases where, as a rule, a few muscles remain partially paralyzed for the rest of the child's life.

There remain, however, a large number of cases in which, as in the sporadic types, a permanent paralysis of some kind is left.

TREATMENT.

During the early stage of the disease at the onset cupping of the back by dry cups applied for a short time only but repeated two or three times a day may relieve the congestion that is present. Ice-bags applied to the spine may have the same effect, and sponging of the body with cool water or with water and alcohol may keep down the fever to a certain extent. As a rule, children in this stage are in great pain and require some sedative. Acetanilid, antipyrin or phenacetin in appropriate doses for the age may be given. It is not unwise to use Dover's powders in connection with the coal-tar preparations. The children should be kept very quiet, as their limbs are exceedingly tender. A brisk purgative should be given, and the nutriment during the first two or three days should be chiefly milk. Dr. Cushing, of Baltimore, has recently proved that the administration of urotropin results in the presence of formaldehyd in the cerebrospinal fluid as demonstrated in his cases of cerebral surgery. This fact, which I can confirm, may be utilized in the treatment of nervous diseases where an infection is suspected, and hence the use of five grains of urotropin every four hours to a child of 8 years and smaller doses for infants may be tried during the onset of the disease or until fever subsides. Salicylate of soda has been given also in the early stage by some observers with apparently good effect. I prefer salicylate of strontium as less likely to irritate the stomach.

After the stage of onset is over and the pain has subsided it is wise to stop medication for two weeks and then begin the use of strychnin, which should be pushed in these cases as far as is consistent with safety. I have seen marked improvement under the use of one-fortieth of a grain of strychnin three times a day to a child of 8; a rather high dosage, to be reached only by progressive small increase over the initial dose. The condition of the muscles can certainly be markedly improved by manipulation, by massage, by rubbing the limbs with oil or cocoa butter, or allowing the child to play daily or twice a day in a warm bath for half an hour or more, or by applications of galvanism, both constant and interrupted. It is especially important from the very beginning of the case to prevent the development of deformities, which, in the majority of instances, are simply due to the action of gravitation on the limb whose ligaments are relaxed and whose muscles no longer act on the joints as ligaments. Proper position should, therefore, be insured by carefully adjusted braces when the child is out of bed and by properly adjusted pillows and little sand-bags to hold the feet in position when the child is in bed. The numerous severe deformities which subsequently require section of the tendons, if neglected, can always be prevented by properly adjusted orthopedic apparatus, and it is never wise to delay the application of such apparatus until the deformity has been produced. The orthopedic treatment of these cases is more important than any other.

5 West Fifty-fourth Street.

DISCUSSION.

Dr. Wharton Sinkler, Philadelphia: The epidemic of poliomyelitis in New York last year was the largest on record. No doubt a great many unrecorded epidemics have occurred. A few years ago a child suffering from poliomyelitis was brought to me from a small town in North Carolina. The parents told me that several other cases had occurred at about the same time as their child's case. There are a number of points of dissimilarity between the symptoms in the epidemic form and the sporadic form of poliomyelitis. The mortality is much greater in the epidemic form. I have seen only one case of complete recovery. The child was treated with salicylate of sodium. I have always felt that the salicylate of soda is a remedy indicated in the treatment of poliomyelitis in the early stages. In the epidemic form there is a more diffused and general involvement of the whole nervous system, involving the meninges to a great extent, which does not exist in the sporadic form. The seasonal relation is the same. A large majority of sporadic cases occur in the hot months of summer, and the same has been the case with every epidemic recorded. I saw recently a child who had had apparently two separate attacks. The right leg was first involved and the paralysis receded; fairly good recovery took place. At the end of three weeks the left leg was involved, and when the child was brought to me there was flaccid paralysis of the left leg.

Dr. Charles K. Mills, Philadelphia: While the disease has not prevailed in Philadelphia and vicinity as it has prevailed in New York, during the last two or more years the number of cases has increased. The disease in our own neighborhood has not received the attention that it should. One general practitioner in Philadelphia had about twenty cases. I saw two or three of these, one of most severe type and yet not fatal, in which the child was paralyzed literally from the neck down, and barely succeeded in breathing and maintaining cardiac action. At the neurologic service at the University of Pennsylvania we have had many cases brought not only from the city but from a distance, from Clearfield county, for instance, where the disease seemed to be endemic.

The probability of the occurrence of a true neuritis in these cases of poliomyelitis is worth remarking. Dr. Starr has referred to the frequency with which pain has been present. In cerebrospinal meningitis I indicated a number of years ago that multiple or diffuse neuritis occurs as part of the disease. On the edge of the epidemic, in the early months of it, I saw two cases of multiple neuritis in children, one about 13 or 14 years old, and the other younger. I have seen a few patients who have completely recovered, and several who have nearly recovered. No cases in my own experience have been fatal, but in several the disease has been of an extremely severe type. I believe in the occurrence of Strümpel's poliomyelitis or encephalitis, and I have seen cases.

F. X. Dercum, Philadelphia: I found a diplococcus in a sporadic case of poliomyelitis some years ago. However, I did not regard the finding as of value. I am convinced that the pain in the epidemic cases which we have had in Philadelphia is much more marked than in sporadic cases. In sporadic cases the pain has, in my experience, been a negligible factor, but during the present epidemic the pain in some cases was atrocious, and was not influenced by salicylate of sodium. It would be interesting if the final conclusion were to be that there are two different affections, similar only in a few points in regard to their symptomatology. Certainly the suggestion that the cases of the present epidemic were contagious would be in keeping with such a view. I have been impressed in the cases that I have seen by the relatively high degree of recovery; the attack had in some cases swept through the nervous system like a cyclone and yet left mere traces behind.

Dr. Frank R. Fry, St. Louis: I believe that in this epidemic form older patients are often attacked, and for that reason some cases are overlooked. Three years ago we had an epidemic in St. Louis, not nearly so extensive as many in the east, of course, yet enough of an epidemic so that we noticed many cases. The general data only and no statistics were collected, showing plainly that there had been an epidemic, and among the cases a number of cases in young adults.

Dr. L .H. Mettler, Chicago: In these forty-four various epidemics, particularly the last one, has there been a partial or complete repetition from year to year of other cases in the same localities? I think Oppenheim has made the statement that almost all his cases of this disease came from one particular locality, not far from Berlin; thus leaving one with the impression that there is an endemic character, at least in some respects, to the trouble. This might account for the various outbreaks at different times and of varying degrees.

Dr. Frank P. Norbury, Jacksonville, Ill.: In central Illinois, three years ago, during the time that poliomyelitis was prevalent in St. Louis, I saw about eight cases. Two occurred in young adults, one a college student, a young man about 18, another in a young farmer of about 25. Both were cases of anterior poliomyelitis.

Dr. William G. Spiller, Philadelphia: Meningitis has been found as a complication in cases of poliomyelitis, and the pain may be caused by the meningitis. The lesions are not always confined to the gray matter in poliomyelitis. I have seen the typical findings in the lumbar region of a spinal cord, whereas sections from the thoracic region of the same cord showed involvement of the white matter. Strümpell's form of polioencephalitis exists. I have examined the specimens from three cases in which the lesions were almost confined to the gray matter in a limited area of the cortex. One was from a case of Dr. Mills, another from a case of Dr. Moleen, and the third from a case of my own. In the late stages of poliomyelitis nerve transplantation may be of service. Often a nerve is cut and inserted into another nerve without transverse division of the second nerve. The results have not always been favorable. The best results may be expected from end-to-end anastomosis. Bikeles cut certain nerves in one leg of a dog and inserted them in another nerve, without cutting the nerve across into which he made the insertion. In another leg he cut the nerves entirely across and anastomosed the central end of one nerve with the peripheral end of another nerve. He allowed the dog to live 294 days after one operation, and 210 days after the other, and then cut the nerves below the point of operation. When a nerve is cut reaction at a distance occurs in its nerve cells, and Bikeles showed that no alteration of the cells of the nerve into which the insertion had been made occurred, whereas alteration followed on the side of the end to end anastomosis; indicating that on this side only had physiologic union occurred after the previous operation. From this experiment we may conclude that in operations on nerves in cases of poliomyelitis our results will be better if we partially or completely divide the healthy nerve before uniting it with the diseased nerve.

Dr. Charles R. Ball, St. Paul: In two cases of poliomyelitis in adults, which I reported several years ago, one a boy of 16 and the other a man of 40, I had the opportunity of seeing those cases during the acute attack. The fever never went high—not over 101—and then perhaps only for a short time—a portion of a day, and yet the paralysis following was quite severe. Is there any relation between the severity of the acute symptoms and the following paralysis? Has Dr. Starr observed whether the residual paralysis left in adults having acute poliomyelitis is apt to be greater than in children?

Dr. A. R. Allen, Philadelphia: We have had at the disposal of the University of Pennsylvania at least two cases of typical anterior poliomyelitis which showed, for a number of weeks after the onset of the symptoms, distinct nerve pain on pressure along the nerves. In one case the tibialis anticus was extremely tender to pressure, and we thought that it was a case of neuritis in connection with antërior poliomyelitis change.

Dr. Henry W. Frauenthal, New York: In the last epidemic treated in the last month, the patients over 10 years of age have recovered early as compared with those who are older. I recall the case of a patient 17 years of age, treated for deformities and joint diseases, in the hospital (which takes in no patient under 14 years of age), who has had two hours' treatment daily with electricity and massage. The boy has made comparatively little progress toward recovery compared with improvement made by patients treated for a short time three days in the week. In my experience patients over five years old do not recover as quickly or as completely as children under that age.

Dr. D. I. Wolfstein, Cincinnati: Dr. Buzzard in a recent article says that many cases of so-called infantile paralysis occur in early adult life, and even in later years. It would be interesting to know whether or not any of the cases diagnosed as infantile paralysis might possibly have been acute cases of this toxic form of neuritis, and whether the differential point that Dr. Buzzard makes in connection with that, the early involvement of the facial muscles, was noted.

Dr. Morton Prince, Boston: I noticed in Dr. Collin's collection of cases in the same epidemic that the third and sixth nerves in these cases were found to be paralyzed. His patients were all below 10 or 11 years of age.

Dr. H. Ostrander, Kalamazoo, Mich.: There is an epidemic of this kind in western Michigan, including twenty-five cases, some of which I saw. In a number of families where children had the disease, there were adult cases presenting acute symptoms of the onset of the disease; they had the rise of temperature, the terrific pain and bowel trouble, but there was no paralysis following.

Dr. M. Allen Starr: In answer to Dr. Sinkler's question about recurrence, there have been cases reported in other epidemics, one by Gieswold, in Norway, of the patient having an attack in one leg with apparent partial recovery, and a second attack nine weeks later in the opposite leg. Wickman records two cases of recurrence at an interval, in one case of eight weeks, and in the other three months. I have never seen a case of recurrence, but I saw a little boy who was attacked last summer with anterior poliomyelitis in the right arm; and I found he had pseudohypertrophic paralysis in both legs and back. The two diseases had naturally been confounded, but it was easy to show that the pseudohypertrophic paralysis had been of gradual onset for the past three years, while the poliomyelitis had come on in the arm as an acute attack. In answer to Dr. Mills and others, the differential diagnosis between neuritis and poliomyelitis is not always an easy one. I have been unable to find on record any cases of distinct demonstration of neuritis associated with poliomyelitis, although the pathologists who have written on this subject have detailed cases of degeneration in the anterior nerve roots and in the anterior nerves passing downward to the muscle. Anything like the acute congestive condition with exudation in the nerve sheath has not been observed, so far as my knowledge goes, and Wickman's pathologic observations and those of Harbitz and Scheel in the Norway epidemic, show a particularly careful record of the condition of the nerves. Pathologically we lack the demonstration of the coincidence of multiple neuritis with anterior poliomyelitis. That multiple neuritis does occur and that it does occur in a toxic type in children I freely admit, because I have seen cases, but I think that they are extremely rare. That multiple neuritis is rare in connection with anterior poliomyelitis is proved by the fact that we do not find conditions of anesthesia of a permanent type or even of a glove stocking temporary type, in cases of anterior poliomyelitis, while that is characteristic of multiple neuritis I am unwilling to admit that the mere existence of pain is a proof of multiple neuritis in connection with anterior poliomyelitis.

In answer to Dr Fry the vast majority of patients in New York ranged in age from 6 to 7 months up to 8 years, but cases occurred in patients aged 32 I witnessed and investigated carefully the epidemic of Rutland, Vt —144 cases—and there saw patients as old as 54 No age is exempt

It seems to me that the proper treatment of the chronic state of the disease is clearly orthopedic. The transplantation of tendons has been a great deal more satisfactory to me than transplantation of nerves I have had nerves transplanted, but not with the good results that I have had in splitting the muscles and tendons, and so making practically new muscles for the children. If you have a single muscle left below the knee you can repair the paralysis of almost all muscles of the foot. There is no relation between the degree of fever and the amount of paralysis, and the residual paralysis is greater in adults than in children There has been no examination of the excreta for the detection of the particular toxin. The recovery is slower and much less in degree in adults than in children. I have two cases in which the third nerve was paralyzed, in addition to several cases in which the sixth nerve was paralyzed. The existence of abortive cases was not recognized until Wickman made his investigations It is important to recognize the existence of cases of extreme fatigue and malaise in children, with unwillingness to move, which do not amount to anything in the way of a true paralysis afterward.

I consider electricity applied to the central nervous system as utterly useless in every particular, and that a lesion of the brain or of the spinal cord can not be affected in any way by the passage of a galvanic, faradic or other current through the central nervous system The muscles can be toned up very well by anything that will cause them to contract; but as for increasing the nutrition of the spinal cord or replacing one little nerve cell by the electric current, I do not believe any body ever did it.

THE OPTIC NERVE CHANGES IN MULTIPLE SCLEROSIS.

WITH REMARKS ON THE CAUSATION OF NON-TOXIC RETROBULBAR NEURITIS IN GENERAL.*

WARD A. HOLDEN, M.D.
NEW YORK.

It seems scarcely necessary to dwell on the established facts of the optic nerve changes in multiple sclerosis. These are familiar through the statistical studies of Uhthoff[1] and those who have followed him. We know that ophthalmoscopic changes in the optic discs are found in about half the cases of this disease, that visual disturbances are frequently early symptoms—sometimes preceding any other symptoms by months or years—that the visual disturbances are often of sudden onset, and, if slight, frequently remain long unprogressive, and if excessive usually improve, the course of the optic nerve changes thus differing radically from the slow, steadily progressive atrophy of tabes.

I shall take it for granted, also, that it is the custom to examine the fundus and determine the fields of vision in every case in which multiple sclerosis is suspected. Optic nerve changes, if present, will help to confirm the diagnosis. Thus ophthalmoscopic changes in the discs will exclude hysteria; and since optic nerve changes are rare in early paresis, if not complicated by tabes (I found the discs normal in seventy consecutive cases of early uncomplicated paresis), one can exclude this disease, into which many cases, diagnosed as multiple sclerosis, develop after they have come into the hospitals for the insane.

It will be more to the purpose to base my remarks on a number of illustrative cases, considering them under several headings.

A. THE PATHOLOGIC CHANGES IN THE OPTIC NERVES IN MULTIPLE SCLEROSIS.

The cause of disseminated plaques of sclerosis in the central nervous system is still unknown. It is agreed that the histologic changes consist of localized vascular disturbances, with exudation of round cells, and of degeneration of the medullary sheaths of the nerve fibers, while the axis cylinders and ganglion cells are long preserved. Hypertrophy of the neuroglia usually fills the spaces left by the disappearance of the medullary sheaths.

The degenerative changes may remain limited to the plaque or medullary degeneration may extend upward or downward. Restoration of the degenerated medullary sheaths often takes place and the fibers then resume their function.

Typical pathologic changes in the optic nerves and chiasma were found in the following case:

Case 1.—A woman, aged 27, died at the Montefiore Home of infection after cystitis and pyonephritis, which were manifestations of multiple sclerosis.

History.—Seven years before her death she fell and dislocated her right hip. A year later she noticed weakness, numbness, and coldness of her right leg, which lasted for two months. Four months later the same symptoms were experienced in her left leg. These cleared up in two months

Eye Symptoms.—About this time there was a sudden diminution of vision and it was said that she was "blind in one eye and color blind in the other." Vision improved, and she was comparatively well for a year and a half. Four years before her death her left leg again became weak and numb. Her gait was staggering. There was disturbance of micturition. There were diplopia, nystagmus, poor vision, slow and monotonous speech, deafness, and poor memory for recent events. Three years befor her death temporal pallor of the discs was noted.

Pathology.—At the Pathologic Institute of the New York State Hospitals, serial vertical sections were made under the direction of Dr. Dunlap, through the optic *nerves, chiasma, and* tracts, and these were stained with Wolter's medullary stain and with hematoxylin eosin. In a section through the optic nerves at the point of their emergence from the chiasma, there is seen (Fig. 1) a diffuse degeneration, particularly in the central or papillo macular bundles of fibers in each nerve, which accounts for the temporal pallor of the optic discs seen in life. This degeneration consists of an absence of a certain number of medullary sheaths in each affected bundle. The degeneration can be followed down the optic nerves toward the eyeballs. Further back in the chiasma there is a sharply outlined oval plaque, in which the medullary sheaths are almost entirely wanting. The affected area appears to be rarified rather than sclerosed, and there is no increase in the number of neuroglia nuclei, and neuroglia fibers form a loosely meshed network (Fig. 2). The degenerations in this case are old, and no inflammatory conditions are found, as was to be expected.

Such being the characteristic pathologic changes in the optic nerves in this disease, it is obvious that they may give rise to a variety of types of visual disturbance.

---

[1] Graefe Saemisch, xi, p. 337.

B. THE TYPES OF FIELDS OF VISION, AND THE CORRESPONDING OPHTHALMOSCOPIC CHANGES IN THE OPTIC DISCS.

The visual disturbances fall chiefly into three groups: (1) Concentric contraction of the field of vision; (2) central scotoma with normal peripheral limits of the field, and (3) a combination of concentric contraction of the field and central scotoma. These types of fields are associated, to a certain extent, with characteristic ophthalmoscopic appearances of degeneration in the optic discs. Discrepancies may occur, however, since in rare instances there may be some degree of papillitis, and, again, a lesion far back in the nerve may cause visual disturbances long before a descending degeneration leads to pallor of the disc, while conversely the clearing up of a lesion in the nerve may lead to improvement in vision while the disc, after once becoming pale, remains so.

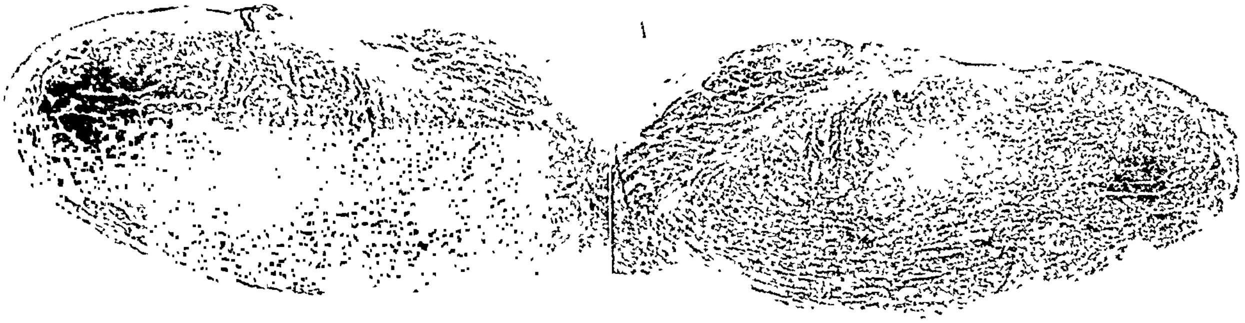

Fig. 1.—Optic nerves in cross section where they emerge from the chiasma. Wolter's medullary stain shows pale areas of degeneration, chiefly in the central bundles of each nerve.

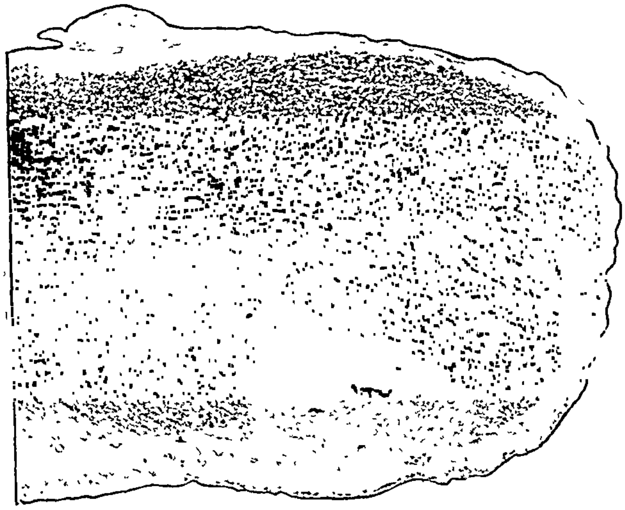

Fig. 2.—A peripheral, sharply-outlined, oval, sclerotic plaque in the chiasma, with a large vessel in its center (below and to the right). Wolter's medullary stain. The fibers which run through the plaque preserve their medullary sheaths in sections anterior to it, but posteriorly a certain degree of ascending degeneration in the optic tract can be made out.

Normally, the temporal portion of the disc is paler than the nasal portion, and while in diffuse degenerations of the nerve, with concentric contraction of the field of vision the entire disc may become pathologically pale, this pallor is always more pronounced in the temporal portion of the disc. The axial or papillo-macular bundle of the optic nerve which is distributed to the region of the macula lutea, the center of distinct vision, lies in the center of the optic nerve as it emerges from the chiasma, but when it has descended to the optic disc it occupies the inferior temporal quadrant of the disc. When the papillo-macular bundle alone is involved, in cases with pure central scotoma, the inferior temporal quadrant of the optic disc alone shows a pathologic pallor.

Concentric contraction of the field of vision is well shown in the following case:

CASE 2.—A man, aged 21, four and a half years ago noticed vertigo and a staggering gait. Six months later tremor of the head and hands came on, and there was difficulty in speaking. Now there is marked nystagmus and great difficulty in walking.

Examination.—Three years ago his vision failed during a period of four months and has since been stationary. O. D. = 20/50; O. S. = 20/30. There is concentric contraction of the fields. On the right side, the contracted limits of the field for a 1 cm. square of white on a black ground are shown in Figure 3 by the heavy unbroken line; the contracted limits of the field for a 1 cm. red square on a gray ground are shown by the broken line. The red square can be seen as far away as five feet, and is seen more clearly at the point of fixation than to one side. The disc presents a marked pallor in its entire extent, except in a narrow crescentic zone at its nasal margin. The outlines of the disc are well defined. The arteries are small, the veins are of normal caliber (Figs. 3 and 4).

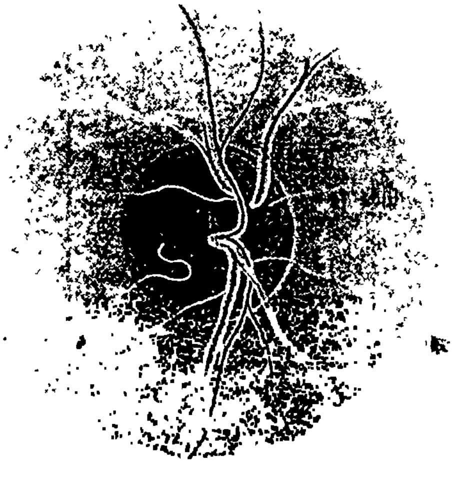

Fig. 3.—Case 2. Concentric contraction of the field for white and red, with well-marked pallor of almost the entire disc.

The next case exhibits a central scotoma.

CASE 3.—A man, aged 29, noticed five years ago paraesthesia of the feet, then weakness and stiffness of the legs, increasing for a year, when he became unable to walk. Two years ago he lost control of his arms. For a time there was diplopia. Now there is constant nystagmus and difficulty in speaking.

Examination.—Five years ago his vision failed gradually for six months, and has since remained stationary. O. D. = 20/50, O. S. = 20/70. For the left eye, the limits of the fields for white, for a 3 mm. black dot and for red are normal, but the red square can not be recognized at a greater distance than eighteen inches, and it is seen at this distance obscurely in a central field 15 degrees in diameter, and more clearly on every side (Figs. 5 and 6).

There is pallor of the left optic disc limited to the inferior temporal quadrant. The outline of the disc is well defined and the arteries and veins are of normal caliber.

The next case illustrates a combination of concentric contraction of the field and central scotoma.

CASE 4.—A woman, aged 27, met with an accident two years and a half ago. Eight months later she had pains in the head, neck, chest, hips and fingers. Her feet felt numb. Now there is constant nystagmus and great difficulty in walking. She has never had diplopia.

Examination.—The vision of the left eye became affected soon after the accident and while there have been fluctuations in the sight, no great change has taken place. O. D. = 20/30; O. S. = 20/100. The right optic disc and fields are normal. On the left side there is concentric contraction of the field for white (Fig. 8). In the central portion of the field red is not recognized in the area indicated in the chart by the dots. The disc is slightly pale in its entire extent and the inferior temporal quadrant is still paler. The outline of the disc is blurred and the veins are dilated.

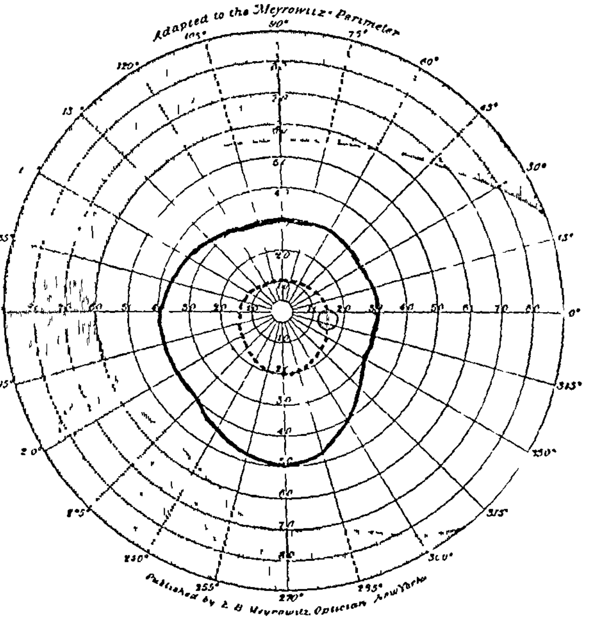

Fig. 4.—Case 2. Diagram of visual field, showing concentric contraction.

These three hospital cases examined recently give one a fair idea of the changes in the visual fields and in the optic discs likely to be found in multiple sclerosis.

C. RETROBULBAR NEURITIS THAT IS PROBABLY AN EARLY SYMPTOM OF MULTIPLE SCLEROSIS.

In the cases described above the optic nerve changes clearly were due to multiple sclerosis. But when visual disturbances, suggestive of multiple sclerosis, are not accompanied by other symptoms of the disease there may be much doubt as to their nature. Furthermore, visual disturbances may precede all other symptoms of this disease for years, or, possibly, since this is sometimes a monosymptomatic disease, the optic nerve disturbances may be the only symptoms.

A case of retrobulbar neuritis suggestive of multiple sclerosis, but unaccompanied by any other pronounced symptoms of the disease, is the following:

CASE 5.—A year and a half ago, I saw a man of 23, who said that the sight of his left eye had become blurred nine months before, and that the sight of the right eye had become blurred three months later.

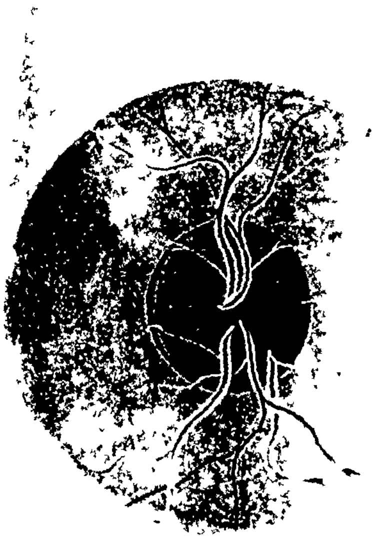

Fig. 5.—Case 3.—A relative central scotoma for red; with pallor of the inferior temporal quadrant of the optic disc, in which lies the papillo macular bundle.

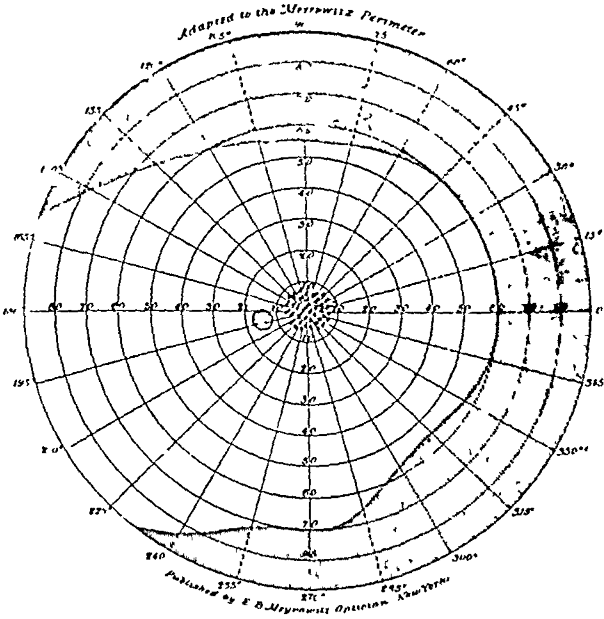

Fig. 6.—Case 3. Visual field. The dotted area represents the relative central scotoma for red.

Examination.—His vision failed rapidly, at first, then remained stationary, and in the few weeks before I saw him, he had noticed some improvement in the vision of the eye first affected. He could count fingers with either eye at a distance of four feet with eccentric fixation. The limits of the field for white for each eye were normal. Red could be seen faintly in the periphery of the field of the right eye, but not at all in the field of the left eye. There was an absolute, circular, central scotoma for white, about 25 degrees in diameter, in the field of each eye.

The right optic disc was slightly pale in its temporal half. In the left eye, in which the visual disturbance was of longer duration, there was a slight general pallor of the entire optic disc, more marked in its temporal half. The outlines of the discs were well-defined, and the veins were slightly dilated. His vision was better in reduced illumination.

Other Symptoms.—An only brother, aged 30, had never had any visual disturbance, hence family retrobulbar neuritis could be excluded. The patient was not under weight, his general health was good, and he complained of no nervous symptoms. Tobacco, alcohol, lead, diabetes, and syphilis could be excluded as causative factors. There were no nasal symptoms. There was a slight tremor of the face and also of the hands, but the latter was not pronounced enough to affect his writing. There was at times a slight nystagmus in extreme lateral directions of the gaze. The knee-jerks were active, but not decidedly exaggerated.

Course of Disease.—Examinations by a number of physicians revealed no cause for the retrobulbar neuritis, and various forms of treatment having been of no avail, it was decided to abandon treatment altogether, and the patient went abroad to travel. A few months later, his sight improved so that he was able to read, and he then resumed his occupation. No other symptoms of multiple sclerosis have appeared up to the present time, nearly two and a half years since his vision became impaired.

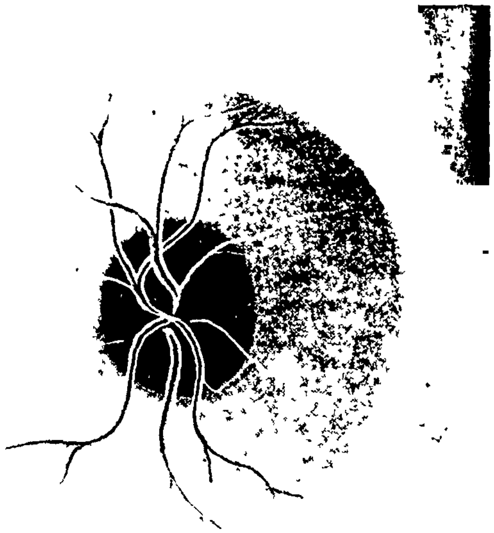

Fig. 7.—Case 4. Concentric contraction of the field for white and for red and also an absolute central scotoma for red. Slight signs of inflammation in the disc and a slight general pallor with more pronounced pallor in the inferior temporal quadrant.

In this case the optic nerve disturbances, both in character and in course, are characteristic of multiple sclerosis, but up to this time, two and a half years after their onset, no corroborating symptoms have developed. Nevertheless, this case seems to me to be one of multiple sclerosis.

D. THE CAUSES OF RETROBULBAR NEURITIS OTHER THAN MULTIPLE SCLEROSIS.

Frank, in Oppenheim's clinic, found that optic-nerve symptoms appeared before other symptoms in 15 per cent. of the cases of multiple sclerosis. Bruns and Stölting found this to be the case in 30 per cent. Marx[2] recently sent for all the patients with retrobulbar neuritis and tobacco-alcohol amblyopia who had been seen in recent years in the Strasburg University eye clinic. Cases of toxic retrobulbar neuritis caused by tobacco, alcohol, lead and the toxemias of pregnancy are diagnosed easily and are placed by themselves. Cases due to syphilis, diabetes and trauma also are diagnosed readily. Among sixteen patients with non-toxic retrobulbar neuritis, whom Marx examined, each at an interval of from three months to seven years after the first observation, six patients were found undoubtedly to have multiple sclerosis, or 38 per cent. In the remaining ten cases he found the most important etiologic factor to be exposure to cold and wet, followed by coryza.

What was the probable cause of the retrobulbar neuritis in these ten cases? It has long been recognized that since the wall of the sphenoidal sinus is, in part, also the wall of the optic foramen, sphenoidal suppuration may lead to blindness. In this country, more than twelve years ago, Dr. C. R. Holmes operated successfully in such a case by opening the ethmoidal and the sphenoidal sinuses and restored the vision of a blind eye. He stated[3] that sphenoidal disease might be the cause in very many instances of obscure cases of retrobulbar neuritis.

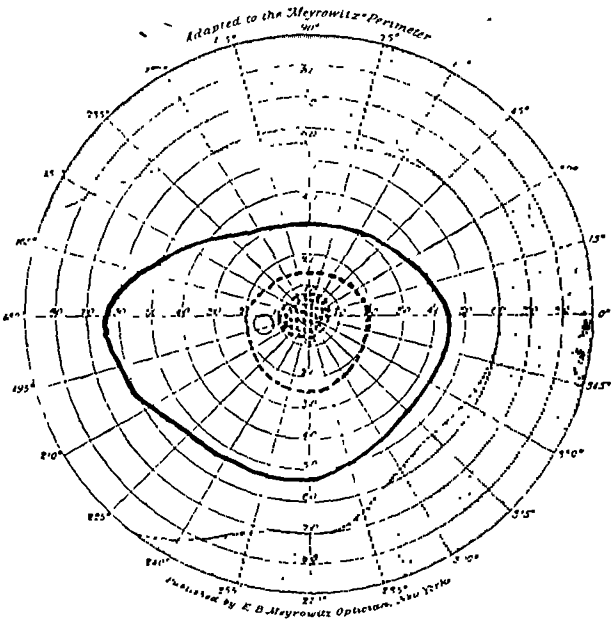

Fig. 8.—Case 4. Concentric contraction of field for white is shown by the heavy unbroken line, and of the field for red, by the broken line. The central dotted area represents the absolute central scotoma for red.

Onodi,[4] working for ten years on the relations between the optic nerve and the accessory cavities of the nose, long ago found that frequently the posterior ethmoidal cells are separated from the optic nerve in the optic foramen by the thinnest possible bony wall, and, furthermore, that the distribution of the blood vessels favors an extension of inflammations from the mucous membrane of the ethmoidal cells to the periosteum of the optic foramen. Thus ethmoidal disease may give rise to an affection of the canalicular portion of the optic nerve, which manifests itself in a central scotoma or perhaps in complete blindness. At first there may be no changes in the disc, or merely inflammatory signs, but later pallor from degeneration of the nerve fibers appears.

---

[3] Arch. Ophth., 1896.

[4] Der Sehnerv und die Nebenhöhlen der Nase, Hölder, Vienna and Leipsic, 1907.

Dr. W. C. Posey, two years ago, described vascular changes in the optic disc and surrounding retina in cases of ethmoiditis. And Dr. Arnold Knapp has recently reported a case of retrobulbar neuritis with central scotoma in which, by removing a portion of the middle turbinate and draining the ethmoidal cells, the vision was restored to normal. He believes that the common cases of retrobulbar neuritis following influenza are of ethmoidal origin. An illustrative case is the following:

Case 6.—Three months ago I saw a woman, aged 30, who, two years before, had noticed a sudden diminution of vision in the left eye, which passed off in the course of a few weeks. When I first saw her there had been a rather sudden complete loss of sight in the left eye two weeks before, and the eye had no perception of light. The pupillary reaction to light also was lost. Medicinal treatment had not improved her condition. The optic disc was swollen, and the retinal veins were dilated and tortuous.

Examination and Treatment.—In the right eye, acuteness of vision and the field of vision were normal, hence the lesion on the left side lay anterior to the chiasma. Since nothing could be discovered in the orbit to account for the complete blindness, a diagnosis of disturbance in the canalicular portion of the nerve was made. Examination of the nose revealed an abnormal middle turbinate on each side. A portion of the middle turbinate on the left side was removed by a rhinologist, so that drainage of the ethmoidal cells was established, and vision in the periphery of the field at once returned. The large central scotoma gradually became narrower, and three weeks after the operation vision in the left eye was 20/20, with a normal field.

Course of Disease.—A few days later vision in the right eye sank to 20/70, with a central scotoma and normal peripheral limits of the fields. The middle turbinate on this side showed more evidence of disease than the other had shown, and removal of a portion of it was followed by restoration of normal vision in the right eye in a few days.

As stated above, Marx reported sixteen cases of non-toxic retrobulbar neuritis, and six of these patients were found later to have multiple sclerosis. Most of the remaining patients gave each a history of coryza preceding the diminution of vision. Is one not justified, therefore, in assuming that some of these ten cases of retrobulbar neuritis were of ethmoidal or sphenoidal origin?

Non-toxic retrobulbar neuritis has long been a mysterious disease, but it would seem now that a little more study might rob it of much of its mystery and teach us that although syphilis, diabetes, neoplasms, injuries and the like may be causes, non-toxic retrobulbar optic neuritis, in the majority of cases, if it does not mean disease of the accessory sinuses of the nose, means multiple sclerosis.

RECAPITULATION.

Disturbances of vision are found in about half of the cases of multiple sclerosis. Usually the dimness of vision is noticed early in the course of the disease, and it may come on long before any other symptoms have attracted attention.

More than half of the patients with multiple sclerosis who complain of failing sight have central scotoma in the field of vision, and the ophthalmologic diagnosis of their condition is retrobulbar neuritis. Toxic cases of retrobulbar neuritis, due to poisoning with tobacco, alcohol, lead, and the toxins arising in pregnancy are readily recognized and diagnosed as toxic. The causation of non-toxic retrobulbar neuritis, however, has often been obscure. We have learned recently that many of these cases are due to sphenoidal and particularly to ethmoidal disease, which involves the optic nerve in the optic foramen.

In my opinion, we shall soon come to the belief that a non-toxic retrobulbar neuritis, if not due to a sinusitis or directly to syphilis, diabetes, a neoplasm, or trauma is, as a rule, a manifestation of multiple sclerosis, although no other symptoms of the disease may be present.

DISCUSSION.

Dr. D. R. Brower, Chicago: There is probably no disease of the nervous system in which mistakes are so frequently made as in the multiple scleroses. A few years ago there was in the Presbyterian Hospital of this city, a woman at the menopause. She had a coincidence of cerebral and spinal symptoms. She had intention tremor, disturbance of speech, spasticity of lower extremities, slight ataxia, exaggerated reflexes and disturbance of bladder. The physician in charge of the case sent the patient to her home in Iowa with the diagnosis of multiple sclerosis and the usual prognosis. The so-called Christian Science was becoming active in her town. She became interested in it and in a few days was cured. From that day she has been a most ardent propagator of the cult—a case of hysteria mistaken for multiple sclerosis. I do not think that sufficent attention was paid to the eye in this case. The concentric limitation of the field of vision in hysteria is quite different from the central scotomata or irregular contractions of the field of vision in multiple sclerosis. I believe that, if an ophthalmologist had been called in consultation, the error in diagnosis might not have been made. Nystagmus is a valuable eye symptom, especially that form developed by forced movements. Disturbances in the innervation of the muscles of the eye are also valuable aids to diagnosis. The various eye symptoms may take place very early, so that the majority of cases demand the combined action of the two specialties in the beginning to make diagnosis certain.

Dr. Peter Bassoe, Chicago (exhibiting Weigert-Pal specimens of horizontal sections through the optic chiasm of a case, material from which he had received from Dr. J. D. Madison, Milwaukee): I call attention to the great extent of degeneration in the optic nerve, normal fibers being found at the periphery only. The patient died at the age of 24 and had been ill for four years with all the cardinal symptoms and marked optic atrophy.

Clinical Notes

A CASE OF MULTIPLE ARTHRITIS DEFORMANS.

ERNEST H. MUSE, M.D.
ROANOKE, VA.

The following is a rare and interesting case of multiple arthritis deformans. There are few such typical cases of this disease on record, and the marked deformity makes this case doubly interesting, as death usually claims such victims before this advanced stage has been reached.

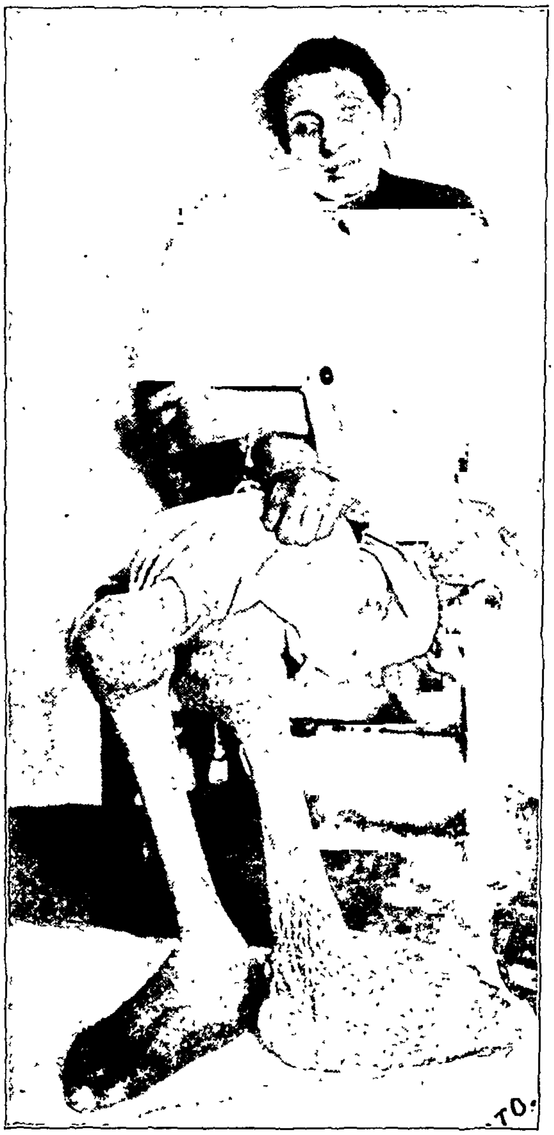
Patient.—A mulatto boy, aged 19. He was born in Botetourt County, Virginia, in 1889; and moved to Roanoke in 1893, where he has since resided.

History.—He went to school in his early childhood, and was apparently in as good health as any boy of his age. During the twelfth and thirteenth years of his life he was delivery boy at a meat stall at the city market, and during these two years he was exposed to a great deal of bad weather. In the fall of his thirteenth year he suffered slight pains in various parts of his body; especially in the joints of the extremities. These pains his physician pronounced of a rheumatic character. They grew worse at times, and then would subside entirely, only to return again at a later date; and on their return they were more severe than during the preceding attack The pains gradually grew worse, and later a thick bloody serum begun to accumulate about the knees, along with a low grade of inflammation. The disease has gradually advanced until the present condition has been reached. About three years ago both of his knees contained an edematous fluid, which pained him considerably. His attending physician aspirated and drew off a quantity of bloody serum. This sufficed to relieve the pain for a short time only; the serum reaccumulating. Another physician was called and he made incisions into the joints, and inserted rubber drainage tubes. Since this the patient has never walked. Contractions of the tendons and muscles soon left him in the condition which he now presents. The knee joints do not seem to be completely ankylosed: but the impaired mobility seems to be due to the contractions of the tendons and muscles, and to the enlargements of the ends of the bones which go to make up these joints. Some two years ago vision in the left eye began to fail, and this gradually grew more marked, until about eight months ago it became totally blind.

Examination.—There is marked ptosis of the left eyelid, which droops so much that it almost covers the pupil. There is only about half normal vision in the right eye. This eye is also gradually growing worse, and will eventually, if the patient lives long enough, become totally blind. The external ocular muscles of the eyes have contracted and caused diverging strabismus. Torticollis has also developed during the progress of the disease, the contraction of the sternocleidomastoid being well-marked. There are well-marked enlargements of the articular ends of the phalangeal bones; atrophy of the muscles, and binding of the skin to the bones between these joints. There are exceptionally well-marked nodules on the left hand. The disease as a whole seems to have affected the left side more than it has the right; especially the eye, hand, knee and foot. The thumb nail on the right hand dropped off about three weeks ago. The thumb nail of the left hand is loosening. The osseous tissue of the elbows and shoulders are enlarged somewhat similar to the condition of the knees, the elbows being much larger than the shoulders. I tried to get a photograph of the naked subject, but he would not submit to it. The muscles between the hips and knees, as well as those between the knees and ankles are much atrophied; in fact they have wasted almost entirely away. The arteries and veins between the hips and ankles are very prominent, and apparently are in their normal condition. The pulsation of the arteries can be felt at almost any point between these joints. Feet: The marked enlargement of the feet is one of the most interesting features of this case. The left foot weighs 12¼ pounds. This enormous weight is principally due to the edematous condition, but the osseous enlargement adds materially. The foot has turned outward and backward to an angle of 78 degrees. The right foot is at about a right angle. Almost all the toe nails on the left foot have come off, and the others are loosening, and will eventually be exfoliated. The splotches on the left foot indicate a dry form of gangrene. The skin is broken in several places, presenting exudating ulcers. The right foot is considerably enlarged, weighing seven pounds. There are no gangrenous or ulcerated areas on this foot, the skin being intact; but there is considerable edema. The nail on the great toe of this foot has been shed, and the others are loosening.

Other Points of Interest.—There are several interesting peculiarities about this case which are well worth emphasizing. At the time of the beginning of this disease this boy was very much darker than the average negro, in fact he was almost black. The pigmentation has made some mysterious disappearance, and he is now almost white, with the exception of about half of the right foot. His hair, before the disease started, had the characteristic nappy appearance which so distinctly marks his race. Now it is straight and black, and resembles greatly the hair of the Indian. The viscera seem to be very little affected. The heart has a very rapid, quick pulsation, the rate per minute reaching 120 on first count and 115 on second. I could not locate any valvular lesions. The lungs are in good condition. The patient breathes freely while in a quiet attitude, but on exerting himself in talking over a considerable length of time he will take a long deep breath, and show other signs of fatigue. He has a good appetite, eating almost anything put on the family table, and assimilating his food as well as could be expected under such sedentary conditions. He keeps his bed most of the time, but gets up once or twice during the day and sits in a chair, but he has to have assistance in getting in and out of bed.

The functions of the liver and kidneys are well preserved, the bowels moving regularly, without the aid of drugs. The urine is normal in quality and quantity, and is passed with ease and painlessly.



The patient has been treated by eight or ten of the best physicians of the city prior to coming under my care, which was about four months ago. There is practically nothing that can be done for him in his present condition that I know of in the way of a curative treatment. I am meeting the symptoms as they arise and relieving them as best I can. The principal treatment that he is getting at present is an occasional anodyne to relieve pain, which is principally in his left foot, and the syrup of iodid of iron as a systemic tonic. He seems to be holding on with remarkable tenacity under this treatment, there being but very little change in his condition since I first saw him.

A BODY ELEVATOR AND SUPPORT FOR OPERATIONS ON THE ABDOMEN AND TRUNK.

GEORGE W. HAWLEY, M.D.
SEATTLE, WASH.

As operative surgery has extended its attack on one organ after another within the body, and operative procedures have become more pretentious and finished, there has arisen the necessity for exposing the various operative fields to better advantage.

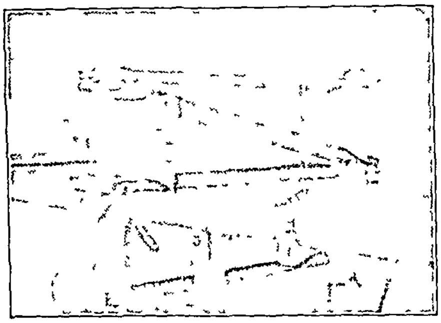


Figure 1

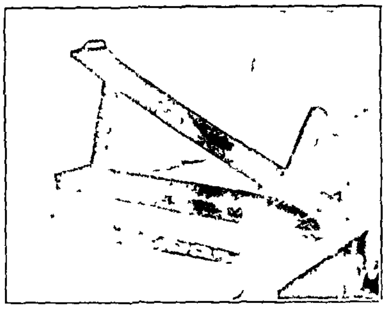

Figure 2.

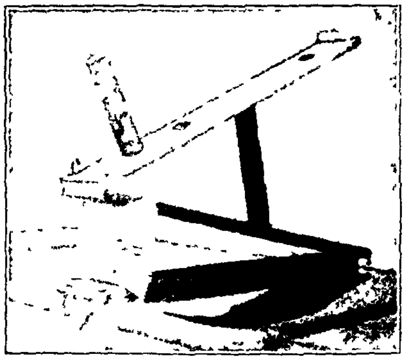

Figure 3.

Fig 1—Showing elevation of both ends of the bar equally, as obtained by the Lilienthal elevator. Used to raise the upper abdomen in operations on the gall bladder, stomach etc, to support the lumbar region in operations on the kidneys and to raise the hips in applying abdominal binder, hip spica, and cleansing the patient after operation. Small sand bags are shown bracing the ends

Fig 2—Shows elevation of one end only (right) with pin in opposite end to prevent the patient from sliding. Pads can be placed over the pin to soften the pressure

Fig 3—Unequal elevation of both ends with pin in the down side. This is about the position and elevation obtained with Cunningham's kidney table

To obtain exposure of any operative field it is customary and natural to raise and support different parts of the body in order that the different structures to be treated may be brought to prominent view and adjacent interfering ones induced to recede out of the way. The time-honored sandbag has long been used for this purpose, but a few substitutes have been taking its place, notably, Edebohl's air cushion, Cunningham's kidney support, and the Lilienthal body elevator attachment on the new Baldwin, Lilienthal, and Markoe operating tables.

Many difficulties are often found in lifting and bracing a patient's limp body on the operating table. Sandbags and cushions frequently fail to maintain the position desired and patients often roll or slip out of position. Cushions, as well as all stationary supports, require attendants to raise the patient while being put in place and provide no ready means of changing the degree of elevation when once in place. The Lilienthal body elevator is a great improvement in many respects, in that the patient's body can be raised or lowered at will without touching the patient, and the position obtained is secure. Its only disadvantages are that it is usually made a stationary part of a table and can not be moved from one part of a table to another or fitted to other tables. Also, it provides only for horizontal elevation.

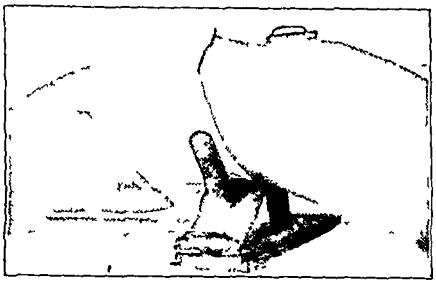

Fig 4.—Elevation of the right side showing exposure and slant of the abdomen. In this position the intestines gravitate to the left side, and the right half of the abdomen is brought up into excellent position for the surgeon as he stands at the left of the table.

Herewith is presented a simple contrivance which can be attached to any operating table and to any part of it. By it elevation of the body from the hips to the shoulders can be obtained, of one side only, of one side more than the other, or both sides equally. As with Lilienthal's elevator, elevation is produced by a thin flat bar placed transversely across the table. By raising and supporting one end of the bar, elevation of the right or left side of a patient's body can be had. By lifting both ends of the bar equally, or one more than the other, both sides are elevated alike, or one more than the other.

The elevation of one side of the body more than the other introduces positions which possess features distinctly advantageous, though but little used and difficult to obtain. In operations on one kidney this has been recognized. In abdominal operations raising one side of the body induces the intestines to gravitate away from that side, in the same way that the Trendelenburg posture induces gravitation away from the pelvis, and the Hartley position away from the upper abdomen. Ordinarily, with the patient flat on the table the operator is required to stoop over the table in order to see the structures directly beneath his incision. For this reason he usually stands on that side of the patient in which he is to make his incision. If, however, he stands on one side of the patient and elevates the opposite side the surface of the abdomen is inclined in the same manner in which one holds a book, the opposite half of the abdomen is brought toward him and into prominent view, the deeper parts are tilted and come into more direct line with his vision, and the necessity and danger of suspending his head over the wound is lessened.

The apparatus here pictured consists of three strips of stout oak three-eighths of an inch thick by four inches wide, with beveled edges and joined by two strong hinges, as shown in the accompanying cuts. The top strip or bar is supplied with a handle at each end, to facilitate lifting the patient. The lower bar is made fast to the table by strong linen straps which pass beneath it. When the ends of the bar are raised they are held in place by sandbags of different sizes or solid supports. A wooden pin pressed firmly into holes at either end of the upper bar prevents the patient from sliding when one end is raised above the other.

The contrivance here described is only a crude model. One made of three strips of rigid metal with polished surface and disjointable hinges would be more suitable. It would be simple to supply the ends with one of the common forms of rachet with or without crank to raise and brace the ends, but the simpler any apparatus the better, and sandbags or braces which fit into notches are sufficient for all purposes.

In using this body elevator it is first securely fastened to the table and placed at the desired level. After the patient is on the table and anesthetized it is seen that his body lies on the elevator at the point to be raised. One or both ends are then lifted by the handles to the proper height and braced. Both ends can be elevated simultaneously by two attendants, or one side at a time by one person. After the patient is raised pillows are tucked under the body in order to distribute the weight and relieve the pressure of the bar. The degree of elevation can be altered at any time by raising one or both ends, and the field can be changed by lowering the bar and patient flat on the table, moving the patient, and again raising the support.

At first sight this elevator may seem to have several bad features. It might appear difficult to securely fasten it to the table. On the contrary, it is practically immovable. It has a tendency to topple over, but only when the attempt is made to pull the patient up or down on the table very far, after the support has been raised. From the photograph one might suppose that the end of the elevating bar might be in the way of the operator or assistant in certain positions. It has not proved so.

Phlebitis and Embolism After Laparotomies.—F. Jayle reports four cases of embolism in patients without the least edema whose convalescence was apparently progressing favorably. They succumbed suddenly the third, fifth, sixth and fourteenth days respectively. In each case the heart was fat and flabby, the venous system hypertrophied, the arterial tension low. Jayle's impression is that extreme dread of the operation predisposes to postoperative phlebitis, as also sluggish bowel functioning. When a patient comes to him from South America or from the French colonies—great meat eating countries—he insists on a preliminary course of treatment of the digestive organs for several days or weeks before attempting an operation. The lesions most frequently followed by phlebitis are fibromas, especially those in the ligaments which press on the veins in the pelvis. The dorsal decubitus also favors phlebitis. He advocates operating on the predisposed in a position approximating the upright and on a very low table. The phlebitis made no sign in the fatal cases reported. When there are distinct symptoms of phlebitis he always feels reassured, as he has never known a case of fatal embolism with well-developed phlegmasia, and others report the same experience. The blood pressure should not be allowed to fall after the operation, and the patient should be allowed to sit up early. His communication is published in the bulletin of the Internes Society, Paris, April, 1908.

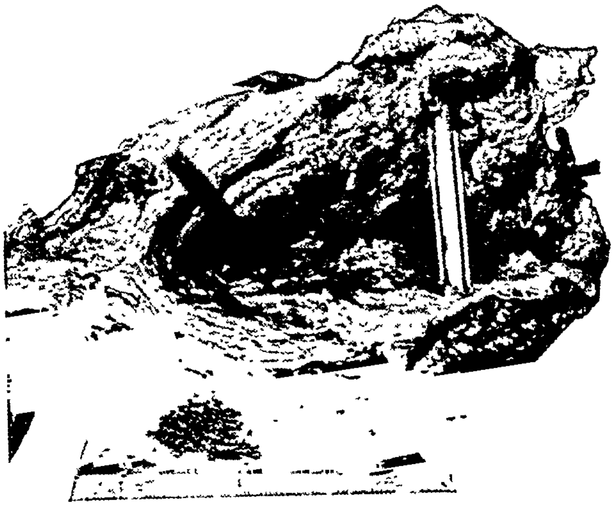
ABSCESS OF UTERUS; HYSTERECTOMY; RECOVERY.

GASTON TORRANCE, M.D.
Surgeon to St. Vincent's and The Hillman Hospitals.
BIRMINGHAM, ALA.

Salva Mersade[1] reports 41 cases of uterine abscess. Of these 22 were from puerperal infection; gonorrhea was the next most frequent cause; five cases were of tuberculous origin. He advises that laparotomy be done in all cases instead of attempting to open the abscess through the vagina. When the abscess is well isolated and the patient young, incising, curetting the cavity and drainage may be practiced. Total hysterectomy will probably be indicated in a majority of cases.

The following is the history of my case which was operated on four years ago:

History.—Mrs. R., age 31, of German parentage; family history negative; menstruation began at 13 years of age, was always regular and normal. She was married at 25; her first child was born fourteen months later; she had a normal labor, but has not been well since then; has had pain in back and in both ovarian regions, with considerable leucorrhea. Another pregnancy occurred two years later. This was also practically a normal labor, but since then her suffering has been very much greater, and she has scarcely been able to attend to household duties.



Abscess of uterus. A probe is passed through the uterine canal and a glass rod is placed transversely in the mouth of the abscess cavity.

Examination.—Vaginal examination shows a retroverted uterus, bound down by strong adhesions, considerable enlargement of both tubes, more marked on the right side; the pain has been much more severe on this side. Very tender on palpation.

Operation.—Under ether a median incision was made and the appendix and right tube and ovary were removed, the adhesions were broken up and what I supposed to be a deep-seated fibroid was found on the fundus, about half way between the right tubal junction and the mid-line. An incision was made to remove the supposed fibroid and opened up an abscess down in the uterine wall, containing about half an ounce of thin yellowish pus, probably of gonorrheal origin. Unfortunately this was thrown out without being examined bacteriologically. I did a supra-vaginal hysterectomy, closing the abdomen without drainage. She made an uncomplicated recovery, and left the hospital in two weeks, and is now in perfect health.

AN EXTRAORDINARY CASE OF HYDROCEPHALUS.

MILLARD KNOWLTON, M.D.
TERRE HAUTE, IND

The following case is of interest because of the unusual size of the head. I first saw the patient about nine months ago and again April 23, 1908, while visiting near Kokomo, Ind

History—The patient a female child was born July 24, 1906, and weighed five pounds at birth It was the first child of its parents The mother and father both come of large and healthy families The mother was slender weighed about 114 pounds, and was 19 years old when the child was born The birth was natural, though the mother stated that she was in labor two days and one night The mother first noticed that the baby's head was somewhat large when it was about two months old, but others had noticed that it was not exactly normal at birth The head has steadily and rapidly increased in size

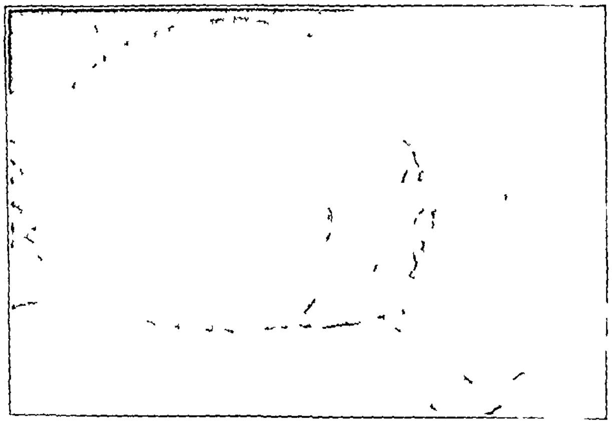

Fig 1—Case of hydrocephalus showing the distended veins elevated eyebrows and clenched fists

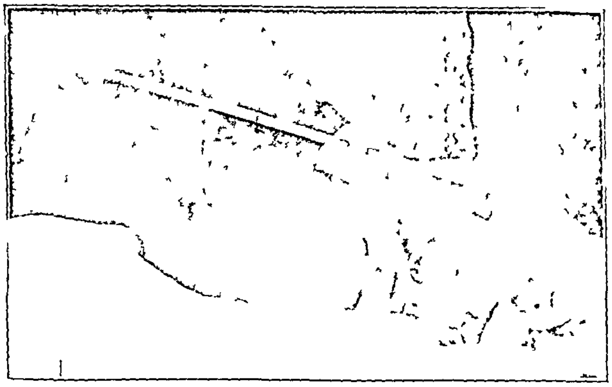

Fig 2—Tape measure held over patient's head to give an idea of proportionate size

Examination—The head measured forty inches in circumference and twenty nine inches from ear to ear over the crown Distance from bridge of nose to edge of hair, eight inches Pulse 140, respirations 40 There were tonic contractions of the muscles giving rise to clenched fists, drawn limbs, etc The mother claimed that this condition had prevailed during the entire life of the child There were thirteen teeth erupted and the mouth apparently was sore There was considerable deformity of the thorax, the anteroposterior diameter being greatly increased There was little if any mentality

The mother of the child has recently (about May 1) given birth to another child, which seems normal in every respect.

LICHEN PLANUS ANNULARIS.

JEROME KINGSBURY, M.D.
NEW YORK.

This case was presented at a clinical session of the Sixth International Dermatological Congress held at the Academy of Medicine, New York, Sept. 12, 1907.

Patient—L S, aged 9, schoolgirl, was born in this country, but of Russian parentage She is anemic and poorly developed Her mother states that the child's health has always been good but that she is extremely nervous and is easily fatigued

Family History—Father has had psoriasis for the past fifteen years and now presents typical lesions. Otherwise the family history seems negative

History of Eruption—The first lesion was noticed on the right arm eight weeks ago It was then about an inch in diameter and at first was thought by the mother to be a ring worm Soon other lesions appeared on the forearms and a little later on the chest, abdomen and legs There is said to have been but little pruritus at any time

Description of Eruption—The annular lesions vary in diameter from half an inch to an inch and a half. The smaller ones are hard and present a firm border with central depression The larger ones are on the arms and abdomen and in places show a fine grayish scaling There are numerous discrete papules on the forearms and trunk These have all the characteristics of the early lesions of lichen planus White patches are to be found on the oral and vaginal mucosa.

Lesion in case of lichen planus annularis

The accompanying illustration gives a good idea of the distribution of the eruption, but fails to show the dermatologic beauty of the individual lesions.

39 West Thirty Ninth Street

Position of Head in Anesthesia—Alexander Blain, of Detroit, in the *New York Medical Journal*, May 9, states that the idea that the patient's head should be lowered is erroneous As a rule, he asserts, the patient's head should be raised on a pillow This is contrary to the teaching of most text books, but patients invariably do better by this method

Therapeutics

Jalap

Jalap is the dried, tuberous root of a climbing vine which grows on the eastern slope of the Mexican Andes and is also cultivated in India. It is named after Jalapa or Xalapa, a city of Mexico. It has a slight smoky odor, and a sweetish and mildly acrid taste. The root yields about 8 per cent of a resin which consists of jalapin and a glucoside, convolvulin or jalapurgin.

The purgative action of jalap seems to be induced by the action of the bile; hence it begins its activity in the duodenum. It causes congestion of the mucous membrane of the intestines, probably increases the secretion of the intestinal glands, peristalsis is increased and profuse, watery discharges are the result. There is often pain, and sometimes griping and vomiting. It seems to be less of an irritant than gamboge, podophyllum or scammony, but excessive doses will produce continuous purging. It causes a movement of the bowels in from three to four hours. It does not cause congestion of the pelvic organs or of the rectum, and is perhaps the mildest of the resinous cathartics. As it can not be detected in the urine it is probably not absorbed, and as it is difficult to detect it in the stools, it is evident that it is partly or completely oxidized.

Jalap is a very useful cathartic, especially when it is desired to cause absorption of effusions. It is especially indicated for this purpose in ascites and in general anasarca, whether from cardiac insufficiency, renal disease or cirrhosis of the liver. It is also indicated when the brain is to be relieved of a too high blood pressure, or when there is congestion of the brain, in meningitis. It is valuable in hypertension and is especially useful when there is venous engorgement from failure of the heart in dilatation in valvular disease, or in failure of the right side of the heart from emphysema. When any of these indications are to be met by the use of jalap it should be remembered that the intake of liquids should be restricted, that the profuse watery discharges may so deplete the blood as to cause it to resorb the water that it finds in the tissues or exudates in cases of dropsy, and in cases of venous engorgement from cardiac insufficiency, that it may relieve the heart of excess of fluid so that the hypostatic congestion may be relieved.

Jalap is also often the drug selected to increase the excretion of toxins by the intestines in renal insufficiency and when uremia is present or impending. In this instanese, if dropsy is not present, considerable water may perhaps be taken to aid the dilution of the toxins in the blood and to promote the excretion by the skin as well as to increase the watery evacuations by the intestines. In other words, jalap, in three or four hours produces watery stools, causing considerable excretion of toxins from the blood, does not cause much irritation of the intestines and if the dose is not too frequent, causes but little prostration. Its taste is not unpleasant, and, therefore, it rarely disturbs the stomach, and for this reason is often selected as a purgative in connection with anthelmintics when such are needed to remove intestinal worms in children.

The preparation of jalap most frequently used is

PULVIS JALAPÆ COMPOSITUS, U. S. P., the compound powder of jalap, which contains 35 per cent of jalap and 65 per cent of potassium bitartrate (cream of tartar). The adult dose is 2 grams (30 grains). This may be repeated in five hours if there are no results. When necessary, this preparation may be given every morning for several days without causing prostration or intestinal irritation.

RESINA JALAPÆ, U. S. P., the resin of jalap, occurs in yellowish brown masses or fragments the fresh fracture appearing glossy and semitranslucent at the edges. When pulverized it is a yellowish gray or yellowish brown powder. It has a slight smoky odor and a somewhat acrid taste. The dose is 0.10 gram (2 grains). This preparation is an ingredient of the compound cathartic pill and of the vegetable cathartic pill, each of which contains 0.02 gram of this resin.

The National Formulary recognizes three preparations of jalap, viz.:

FLUIDEXTRACTUM JALAPÆ, dose 1 c.c., or 15 minims.

TINCTURA JALAPÆ (20 grams of jalap in 100 c.c.), dose 5 c.c. (1 fluidram, a teaspoonful).

TINCTURA JALAPÆ COMPOSITA contains in each 4 c.c. (1 fluidram) 0.50 gram (7½ grains) of jalap and 0.13 gram (2 grains) of scammony. The dose is a teaspoonful.

These tinctures or alcoholic extracts of jalap do not quite represent the whole activities of the drug, as part of the activities are extracted only by water. The alcoholic extracts are said to be more griping than the aqueous extracts.

℞

	gm		
Pulveris jalapæ compositi	10	or	ʒiiss

Fac chartulas 5.

Sig.: One powder, with water, and repeated in five hours, if needed.

Or

℞

	gm		
Pulveris jalapæ compositi	5	or	gr. lxxv
Hydrargyri chloridi mitis	1		gr. xv

M. et fac chartulas 5.

Sig.: One powder, with water, and repeated in five hours, if needed.

Or

℞

	gm		
Pulveris jalapæ compositi	10	or	ʒiiss
Potassii et sodii tartratis	50		℥ii

M. et fac chartulas 10.

Sig.: A powder, with water, daily, before breakfast.

Pulmonary Hemorrhage

The question of the proper treatment of this condition or emergency constantly recurs and it seems to be necessary to reiterate the advice that the blood pressure should not be raised by such drugs as ergot, digitalis, etc., with the idea of stopping the bleeding. All hemorrhage from the lungs unless it is from an aneurism, tends to stop, but the proper treatment for the condition is to lower the blood pressure with nitrites.

At a recent meeting of the American Therapeutic Society in Philadelphia (May 7-9, 1908), Dr. Lawrence F. Flick, Philadelphia, stated in a paper which he read on the treatment of tuberculosis that whenever he found a pulmonary second sound accentuated or increased in force he put the patient immediately on nitroglycerin, and in this way he believed he minimized the danger and frequency of hemorrhages.

Dr. Albert P. Francine, in the *Pennsylvania Medical Journal*, January, 1908, very ably discusses the treatment of hemoptysis. He uses the official spiritus glycerylis nitratis in one minim doses immediately on the occurrence of pulmonary hemorrhage, and repeats the dose at two hour intervals, or oftener in severe cases, and in severe hemorrhage has given a minim (two drops) every half hour for four or five doses. If the hemorrhage is alarming and the patient is nervous he administers ¼ grain of morphin with 1/150 grain of atropin, hypodermatically. It is often advisable to use morphin to quiet the patient's nervousness in pulmonary hemorrhage, but ⅛ grain, or one half the above, is almost invariably sufficient. If this small dose is administered atropin is then not needed to stimulate the respiratory center or to prevent the overaction of the morphin, and as it is a vasoconstrictor, it is best not to administer it.

Francine lays down the usual rules for the immediate treatment of this condition, viz., absolute rest flat on the back with one or two pillows as the patient prefers. Talking must be forbidden. No warm drinks, alcoholic or otherwise, are allowed, and no solid food is permitted. Cracked ice in small amounts may be given to dissolve in the mouth, and perhaps a light weight flat icebag may be put over the heart to quiet its overaction. Similar icebags may be placed over the site of the bleeding if deemed advisable. Strapping the chest on the affected side and limiting its mobility is sometimes of service, and Francine speaks of the occasional necessity of bandaging the extremities so as to retain the blood in them until the hemorrhage ceases. If this is done the bandages should be loosened gradually and not all at once, so that too much blood will not be thrown into the lungs at one time.

It is probably rarely advisable in pulmonary hemorrhage to do transfusion with blood, salt solution, or any other solution, or even to do hypodermoclysis.

Francine thinks that after the arrest of the hemorrhage the patient should be kept in bed at least ten days. This, of course, depends on the amount of the hemorrhage and its cause.

Francine advises the usual treatment to prevent hemorrhage, viz., the administration of calcium chlorid or lactate, and the feeding of gelatin, as a jelly. He cautions against using large doses of calcium chlorid too long, as it tends, in large doses, to interfere with the coagulation of the blood. This caution was concurred in by Dr. Meyer Solis-Cohen, of Philadelphia, in discussing Francine's paper; he stated that Dr. A. E. Wright, of London, has shown that when large doses of calcium chlorid are given for some period, the coagulation of the blood is interfered with. Therefore, after two or three days of the ordinary dose of calcium chlorid, it is well to suspend its administration.

℞.	gm. or c.c.		
Calcii chloridi	5		gr. lxv
Acaciæ granulatæ	15	or	ʒiii
Aquæ cinnamomi	100		℥iii

M. et Sig.: A teaspoonful, in plenty of water, every three hours.

Calcium chlorid, in spite of the mucilage, is irritant to the stomach and sooner or later causes considerable irritation, consequently the following tasteless preparation is the better:

℞.	gm.		
Calcii lactatis	6	or	ʒiss

Fac chartulas 20.

Sig.: One powder, with water, every three hours.

Colocynth.

Colocynthis, U. S. P. (genitive, colocynthidis), is the peeled, dried fruit of a climbing vine which grows in the Eastern Hemisphere. It is also called bitter apple, or bitter cucumber, as the fruit resembles a small orange or gourd. The part of the fruit used for medicinal preparations is the pulp, the seeds of the fruit being discarded. The pulp contains about 0.6 per cent. of an amorphous glucoside, colocynthin, which is the active principle. The taste of colocynth is bitter, and its active principle is soluble in water and alcohol.

In small doses it increases the flow of saliva, and may act as a stomachic, but in larger doses it is irritant to mucous membranes and may cause vomiting. It increases the intestinal secretions and stimulates peristalsis, causing copious watery movements, and if the dose is large it causes severe colic. A large dose may cause gastroenteritis, with bloody stools, and by its irritation may indirectly cause abortion, as may the other irritant cathartics. It may act as an hepatic stimulant, and has been said to have slight diuretic action, showing that some of it may be absorbed.

This drug is rarely prescribed alone on account of its irritant properties, it being better to use a small dose of it combined with other cathartics than a large dose. Colocynth in such small doses has long been used in habitual obstinate constipation, and perhaps most frequently as the compound extract. It should be avoided in all conditions of gastrointestinal inflammation, peritoneal inflammations, and in pregnancy.

There is probably no real good reason for the administration of colocynth. As previously stated in this discussion of cathartic drugs, when an active purge is needed drugs other than the drastic cathartics are better and safer. In chronic constipation even small doses of the irritant cathartics tend to make the condition worse; they are certainly not curative. If vegetable cathartics are desired to produce large watery stools, jalap or elaterium are the best drugs to use.

The dose of colocynth is 0.065 gram (1 grain).

The official preparations are:

Extractum Colocynthidis, extract of colocynth. Dose, 0.03 gram (½ grain).

Extractum Colocynthidis Compositum, compound extract of colocynth. This is composed of 16 per cent. of extract of colocynth, 50 per cent. of purified aloes, 6 per cent. of cardamom, 14 per cent. of resin of scammony and 14 per cent. of soap. The dose is 0.50 gram (7½ grains). This preparation is an ingredient of the compound cathartic pill, and of the compound vegetable pill. Colocynth is also an ingredient of several National Formulary pills.

Cardiospasm.

This is a name applied to a spasmodic contraction of the cardiac extremity of the stomach, and is, perhaps, a more frequently undiagnosed condition than has been thought.

Dr. Charles A. Wingerter, of Wheeling, W. Va., in the *West Virginia Medical Journal*, December, 1907, describes this condition. It occurs in "two forms: as a transitory paroxysmal affection lasting a few hours or even a couple of days, or as a chronic condition which may extend over a number of years." The acute cramp is short and painful, and is difficult to diagnose. The chronic type of cardiospasm is a more serious affection, as it interferes with the general nutrition of the patient and soon makes him an invalid.

Wingerter lays stress on the order of the symptoms as diagnostic, viz., early spasmodic pain, later regurgitation, and still later, retention of food a greater length of time after the meal before the regurgitation takes place. The pain comes on suddenly, and often radiates to the back or neck. In the intervals the patient is apparently well. After some weeks this spasm of the cardia causes a dilatation of the lower end of the esophagus. From this time on the pain, distress and regurgitation are more or less continuous, and emaciation begins. Soft food may still pass through the narrowed cardia, and if enough liquid and soft food is taken, the nutrition may keep fairly good and the regurgitation from the diverticulum may even become less frequent. The reaction of this regurgitated food is always alkaline, it is not acid, showing that it did not come from the stomach.

The cause of cardiospasm may be an ulceration, a new growth, hyperchlorhydria, or hyperesthesia of the mucous membrane at the cardia. This, of course, may occur with neurasthenic and hysterical patients, but is probably often present when patients are considered neurasthenic and may be the cause of the neurasthenia. It occurs in both sexes and at any age.

In the treatment of this condition, of course, if possible all local irritation must be removed, as gastritis or hyperchlorhydria. Some patients have the spasm of this muscle as a neurosis, especially when certain articles of food are eaten, particularly when by some previous experience they have found that such and such a food was followed by this sudden pain and perhaps regurgitation. Such patients need suggestive treatment, as, if the patient can be made not to expect the attack, almost any food may be taken without harm. A spasm being present, morphin or codein will stop it. Antipyrin has been recommended, and some patients do well with bromids. In its primary stage, no tangible cause being found, the patient should be treated as a neurotic. This means institution of any rest cure, change of climate, massage, hydrotherapy or psychopathic treatment deemed advisable.

When the cardiospasm can not be relieved by any of these means and the condition has become chronic, operative dilatation of the cardia must be done, either by esophageal dilators or by opening into the stomach and dilating from below.

An article on this subject, with a report of forty cases, will shortly appear in The Journal.

Iritis.

Dr. Aaron Brav, Philadelphia, (*New York Medical Journal*, Feb. 22, 1908), carefully describes the treatment of this frequent inflammation of the eye. He says that it is a disease of long duration, requiring from six to twelve weeks to effect a cure, a short duration depending entirely on the prompt application of therapeutic measures. The disease is subject to "remissions, exacerbations and recurrences, and in no other ocular disease is the clinician confronted with so many problems on the prompt solution of which depends the ultimate success of the treatment." The recognized causes of iritis are "syphilis, rheumatism, tuberculosis, scrofulosis, malaria, anemia and the infectious fevers."

Dr. C. Higgins, London, senior consulting ophthalmic surgeon, Guy's Hospital (*The Lancet*, April 25, 1908) states that iritis is frequently due to the poison of gonorrhea, although the original infection may have occurred many years before. He thinks this is very frequent in men; perhaps rare in women. The results of this gonorrheal iritis include all the serious consequences to the eye to which iritis is prone.

Brav considers the treatment of iritis under the following headings:

1 To give complete rest to the inflamed organ until all the inflammatory signs have subsided.

2. To relieve pain so as to enable the patient to sleep well and allow Nature's recuperative powers to exert their influence.

3. To prevent, so far as possible, any serious sequelæ, such as the formation of posterior synechiæ."

He says that as a routine practice, eye lotions are not needed, and that irritating eye washes are positively contraindicated. Both eyes should have absolute rest from use, even if but one is affected. Smoked glasses should be used, so that the patient may not be confined to a dark room, although during the acute stage the patient should be in bed and bright light prevented from entering the room. When the pain subsides the patient is better out of bed and in the open air. The diet should be mild and non-stimulating, as in any other acute inflammation, and at the beginning of treatment a good purgative, best perhaps calomel, should be given. Brav gives magnesium sulphate every morning, to be repeated in the evening, if necessary, as:

℞.	gm. or c c.		
Magnesii sulphatis	50		℥ii
Syrupi limonis	50	or	fl℥ii
Aquæ	ad 150		ad fl℥vi

M. et Sig.: A tablespoonful, in half a glass of water, before breakfast.

The most important drug in the treatment of iritis is atropin, which should be used in sufficient doses to produce its full physiologic effect on the pupil. When used in the eye it rarely produces poisoning in the adult, but in children should be used with care. Brav uses a 1 per cent. solution, as:

℞.	c c.		
Atropinæ sulphatis	10	or	gr iss
Aquæ destillatæ	10		flʒiiss

M. et Sig.: One drop in the affected eye every hour until the pupil is dilated; then one drop every eight hours.

[All strong preparations of atropin or similar drugs should be labeled "poison."]

In children a 0 5 per cent. or 0 25 per cent. solution should be used, as deemed advisable, but when atropin causes unpleasant symptoms Brav suggests the following:

℞.	c c.		
Duboisinæ sulphatis	035	or	gr ½
Aquæ destillatæ	10		flʒiiss

M. et Sig.: One drop instilled into the affected eye every eight hours. Or:

℞.	c.c		
Scopolaminæ hydrobromidi	015	or	gr ¼
Aquæ destillatæ	8		flʒii

M. et Sig.: One drop instilled into the affected eye, three times daily.

If undesirable symptoms from the action of atropin occur, such as very uncomfortable drying of the throat, palpitation, flushing of the face, and cerebral excitation, then the stronger atropins must be discarded and homatropin used.

℞.	c c		
Homatropinæ hydrobromidi	40	or	gr vi
Aquæ destillatæ	10		flʒiiss

M et Sig.: One drop in the affected eye every hour.

[If both eyes are inflamed, the strength of the above preparations, in order for a drop to be used in each eye, must be reduced.]

During the course of the inflammation the tension of the eye must be carefully watched lest glaucoma develop, though a temporary increase in intraocular pressure is often seen. As soon as the eye shows increased tension, Brav thoroughly evacuates the bowels, gives absolute rest, and stops the atropin. If the tension does not then in a few hours decrease he uses escrin, as:

℞.	c c.		
Physostigminæ sulphatis	03	or	gr. ½
Aquæ destillatæ	8		flʒii

M. et Sig.: One drop in the affected eye every hour.

Brav says that it is not often necessary to have recourse to this treatment, and it is rarely necessary to employ surgery to prevent glaucoma from iritis.

The value of atropin in iritis is to dilate the pupil and thus to prevent posterior synechiæ. It also contracts the iris, thus reducing congestion, and paralyzes the ciliary muscles, thus giving the iris absolute rest.

If the pain from the inflammation is not stopped by the atropin, hot moist compresses, frequently changed, should be employed. Poultices are not needed. If the pain persists in spite of such treatment, leeches should be applied, one or two to the temporal region, care being taken to avoid the large blood vessels. If in spite of such treatment the deep seated pain in the orbit continues, so as to prevent sleep, morphin must be used, and best hypodermatically.

If the iritis is due to rheumatism, salicylates are advisable, and Brav recommends the following:

℞.	gm. or c.c.		
Sodii salicylatis	15		
Potassii iodidi	15	or	āā, ℥ss
Syrupi sarsaparillæ compositi	100		fl℥iii

M. et Sig.: A teaspoonful, with plenty of water, every four hours.

Brav finds suprarenal solutions useless, and perhaps harmful.

Cocain may be combined with atropin at times, as:

℞.	c c.		
Cocainæ hydrochloridi	03		
Atropinæ sulphatis	03	or	āā, gr ss
Aquæ destillatæ	8		flʒii

M. et Sig: One drop instilled into the affected eye, every three or four hours, if necessary.

The treatment of hypopyon or posterior synechia is a subject for a specialist.

As it is stated that at least 50 per cent of iritis is caused by syphilis and that mostly in the secondary stage, constitutional treatment during such iritis is that of the syphilis, and mercury is the important drug. Brav thinks it is best administered in the form of an ointment, and advises the rubbing on of 4 grams (1 dram) of the unguentum hydrargyri into the skin twice daily, choosing different parts of the body at each application. If symptoms of mercurialism occur, of course the drug should be temporarily stopped, and during its administration alkaline mouth washes should be used.

When the inflammatory symptoms are declining Brav finds potassium iodid of value in promoting the absorption of the inflammatory products. Syphilis having been the cause of the iritis, of course it must be long treated else the iritis may recur, as well as other symptoms of syphilis.

If rheumatism is the cause of the iritis he would not only give salicylates, as intimated above, but during the height of the disease he would give large doses, as a gram of sodium salicylate (15 grains) every four hours, during the daytime.

After the iritis has subsided, especially after antisyphilitic or antirheumatic treatment, the patient generally needs iron

Dr. Higgins, in the article above referred to, says that the treatment of gonorrheal iritis is most unsatisfactory. Mydriatics (atropins) irritate, and rise of tension in the eye is of frequent occurrence; consequently they must be used with caution. He believes in hot fomentations to the eye, and in the value of leeches, and he also sounds a note of warning against the use of suprarenal solutions and cocain. The first effect of their action is satisfactory, but the after-effects are harmful.

For Warts.

SATURDAY, JULY 11, 1908.

SNAKE POISONING IN THE UNITED STATES.

Under the above heading is compiled by Dr. Prentiss Willson a valuable summary of a topic which should be familiar to every practicing physician.[1] There are few localities in the United States in which poisonous reptiles may not be found, at least occasionally, and still more widely spread are harmless snakes that are popularly believed to be deadly. The same instinct which causes almost every man impetuously to ruin his trout rod or midiron on any innocent little reptile that strays across his path causes every mother of a snake-bitten child to believe that all snakes are deadly, and every physician is liable to be called on to determine whether or not a certain snake is poisonous. He should know, therefore, that besides the rattlesnakes there are but three species of poisonous snakes in the United States, and all are easily recognized. One, the coral snake, has but a narrow range of distribution in the southern part of the country and is distinguished by its brilliant markings; the other two, the water moccasin and the copperhead, are characterized like the rattlesnake by the presence of a deep pit between the eye and the nostril and by undivided ventral scales on the tail. All the other snakes in this country are harmless, and for the most part useful members of society, destroying insects, field mice and other pests, and entirely undeserving of the ignorant persecution they suffer on account of their wicked relatives. If this fact were universally appreciated by physicians much unnecessary anxiety and undesirable therapeutics would be spared.

Willson has collected from the literature and from private sources 740 cases of poisoning by snake bites in the United States, and his studies make it very apparent that we need more careful clinical reports of cases of snake poisoning than are at present to be found in the literature. Thorough autopsies are especially needed, there being but four recorded and these so incomplete as to be nearly worthless. Of 566 bites in which the species of snake was known there were 408 cases of rattlesnake bite, 97 cases of copperhead bite, 53 cases of water moccasin bite, and 8 cases of coral snake bite.

Credit for the earliest studies of the nature of snake venoms comes to America, the pioneers having been Bonaparte, Weir Mitchell and Reichert, and much of the more recent work of importance has been produced in this country. Snake venoms are remarkably complex poisons, differing in different species of reptiles, among the ingredients having been found fibrin ferment and antiferment, proteolytic enzymes, cytotoxins for red corpuscles, leucocytes, endothelial cells, and, especially important, the neurotoxins. The venoms of our poisonous American snakes are characterized by producing very severe local effects at the point of injection, and hemorrhages throughout the body, while they affect the central nervous system much less than the venom of such snakes as the cobra. For equal doses the water moccasin and copperhead venoms are more toxic than rattlesnake venom, but the large size attained by some species of rattlesnakes makes them much more likely to inject a fatal dose than the smaller copperheads. Of the 740 cases collected by Willson, 78, or 10.5 per cent., were fatal, and in these statistics the water moccasin seems to be especially deadly, being surpassed in this respect only by the largest species of rattlesnakes.

It seems possible that, in some localities, the treatment of snake bite is more dangerous than the disease. Uncleanly local treatment of the wound, when the resistance of the tissues is greatly lowered by the venom, favors septic infection, while alcohol poisoning is often enough more serious than the snake poisoning. Nothing could be more irrational and dangerous than the popular notion concerning the antagonism of whisky and snake bites, and Willson reports that several of the fatalities in his series were directly due to alcohol rather than to the bite. In one case a boy of 3 years was given over a pint of whisky! Careful local treatment of the wound, directed toward lessening absorption and avoiding infection, together with logical symptomatic treatment, offer the best hope in these cases; and raising the weakened blood pressure by adrenalin, saline infusion and abdominal compression is a valuable procedure. The outlook for antitoxin therapy does not seem to be promising, for, in the first place, it is doubtful if the morbidity and mortality from snake bite in the United States will ever warrant the commercial production of antisera specific for rattlesnake and moccasin venom, which is a far more difficult task than the preparation of serum for cobra venom.

Such a thorough analysis of the subject of snake poisoning in the United States as is provided in the article quoted above has long been needed, for general information on this topic is decidedly meager and strongly tainted with local traditions and superstitions. We recommend its careful study by all physicians practicing in snake-infested communities.

SPECIAL TRAINING FOR ATTENDANTS IN INSTITUTIONS FOR THE INSANE.

A novel and interesting educational experiment is to be inaugurated this summer by the Chicago School of Civics and Philanthropy. Under the leadership of Miss

---

[1] Archives of Internal Medicine, June, 1908, p. 516.

Julia Lathrop, for many years a member of the Illinois State Board of Charities, and now director in this school, a summer course has been arranged for attendants in institutions for the insane and mentally defective. The course has been planned with skill and originality, the object being to show the educational value of occupation, and to afford practical training in those handicrafts which are familiar in kindergartens and manual training schools. In addition, lectures are offered on the elements of psychology, pedagogy and psychiatry and on sociologic subjects. Thus the attendant is to be given training which will fit him to undertake new and important duties in the care of the insane, making of him a teacher and not merely a custodian.

It is true that occupations of various kinds have already been introduced into many institutions, and in some there are even teachers of manual training. But these advantages are offered only to the better class of patients, and the larger number—many of whom need occupation, although they are incapable of learning a handicraft—remain unprovided for. We are all familiar with the discouraging aspects of the typical insane ward, the rows of cleanly dressed patients seated in absolute idleness for hours together, their attendants satisfied with supplying their bodily needs and making no effort to rouse and stimulate them, or with the no less discouraging "restless ward," where so long as the patients give no serious trouble they are left quite without direction for their activities. The Chicago school aims to fit attendants to teach occupations suited to all grades of patients, from simple, childish games to skilled handicrafts. Many a patient just emerging from the depressive stage, many restless patients who for lack of occupation become "dangerous," may be greatly helped by judiciously planned work, and, just as in the education of children games are recognized as of great value, so in the re-education of retrograded minds games can be used to bring back the capacity for muscular coordination, for self-control and cooperation with one's fellows.

The promoters of this novel scheme state that they offer the course to attendants rather than to nurses because the attendants are the constant companions of the patients and all efforts to educate the latter must succeed or fail according to the attitude of the attendants. It has been repeatedly pointed out by all who are familiar with the workings of asylums for the insane that the crux of the situation is the character of the attendant.[1] The sporadic efforts at reform instituted at moments of public indignation over some scandal leave little permanent result so long as they fail to strike at the root of the matter—the personnel of the attendants. In all asylums for the insane the complaint is made that it is so difficult to get a good class of attendants, and yet very little is done to train and improve the material which is at hand. The life of an attendant in an insane asylum is strenuous, joyless and singularly isolated. Such an institution is usually a little world in itself, and the ideas and changing views of the outer world are slow in penetrating. Routine rules supreme, with all its warping and deadening influence. The standards of the attendant are satisfied when a certain modicum of physical well-being is provided for his patients, but the real purpose of the asylum—the re-education and rehabilitation of diseased minds—does not cross his horizon.

The proposed summer school in Chicago represents the first effort of this kind to transform the asylum attendant into an intelligent teacher and to substitute educational for purely custodial care. It is to be hoped that the school will achieve its purpose and that it will inaugurate a new system of training for those in charge of the insane in other states as well as Illinois.

REGISTRATION OF VITAL STATISTICS IN PENNSYLVANIA.

The first "Annual Report of the Commissioner of Health of Pennsylvania," which has just appeared—we do not know why it is so belated—covers the work done by the Department of Health of that state from June 6, 1905, to Dec. 31, 1906, and represents the results of the application of recent legislation to the hygienic affairs of a great state. One of the first advances made is the addition of a number of communicable diseases to the list of those usually required. This innovation has been very successful. One of the most notable advances is the registration of vital statistics. Previous to the enactment of the law of May 1, 1905, the collection of vital statistics in Pennsylvania was in a very unsatisfactory condition. The working of the new law has enabled the state to be included in the registration area of the United States Bureau of the Census. The law is an excellent one and has been used as a guide by the Committee on Medical Legislation of the American Medical Association in drafting the model law recommended for adoption by states lacking an adequate vital statistics act. The essence of the Pennsylvania law is that the work of collecting, reporting and registering vital statistics shall be done by paid officers of the state, who shall be under the control of the state board of health. The keynote of the Pennsylvania administration is compulsory obedience of the reasonable requirements of the law and infliction of the penalties of the law in cases of its violation.

One sad feature revealed by the statistics is the increase in suicides and especially in suicides of children. The rapid increase of homicides also calls for investigation and explanation. The birth statistics indicate a slight reduction in the birth rate. The shortening of the child-bearing period by late marriages due to the entrance of women into gainful occupations, is held in part responsible for this situation.

A matter of great importance in which Pennsylvania is taking advanced ground is the prevention of the pollution of streams by municipal or private action. The need of such action is only too apparent. The law makes ample provision for regulation by the board of health of the state, but in many cases a strict enforcement of the provisions of the statute would work great hardship to communities already burdened with debt to the limit, and hence unable to make the necessary alterations to prevent pollution of the stream into which their sewage is emptied. In such cases the commissioner has been considerate and has endeavored to coöperate with municipal authorities, and reasonable delay is allowed. Extensions of the sewerage system must, however, be made in compliance with plans contemplating treatment works for the purification of sewage in the future.

---

[1] Beers: The Mind that Found Itself.

Much dependence is placed on education of the public in furthering the work of the state sanitary authorities. This is applied with regard to communicable diseases, disinfection, water protection, sewage disposal, the antituberculosis movement and other matters within the sphere of public sanitation. The report, as a whole, indicates a new era in home and public sanitation for Pennsylvania, which, it is hoped, other states will follow.

VACATIONS AND HEALTH.

Vacations are taken mainly with the idea of improving health, yet it often happens that people return to their homes suffering from some form of ill health due to lack of care, and frequently they need additional rest after their return. Vacations during hot weather are especially likely to be followed by unfortunate consequences, for often they have to be taken in unusual surroundings, the sleeping quarters may be more cramped than at home, the food may be unusual and may be eaten irregularly, and the exposure to the sun with unaccustomed exercise may create a condition of lowered vitality which heightens the danger from toxic substances from food, so much more likely to spoil in hot weather, and from infectious bacteria, which grow so much more luxuriantly at high temperatures. In a word, there are so many dangers that the weeks of intermission from a busy occupation may prove anything but the re-creation it is hoped to be and may instead have at least annoying consequences. This is as likely to be true for physicians as for their patients, and there are certain warnings that need to be emphasized at this time.

The old Romans succeeded in conquering the world as much by their ability to maintain the health of their troops in their various campaigns as by the courage and organization of their soldiery. Some of the maxims of their army regulations would be worth keeping before the mind of the vacation tourist who wanders far from home and into unusual conditions during the summer. One of the principal of these was: "In the land of the enemy beware of the water and certain times of the day that the inhabitants of the country deem dangerous." Another was: "Avoid countries with swamps which are sources of diseases, and deserts and mountains without trees." A third that is especially applicable at this time of the year was: "The soldier must not be without protective shelter. A man must guard against the rays of the sun, and begin the day's work very early." These wise old Romans realized just what were the special dangers of people traveling far from home. These were the water, certain times of the day, the heat of the sun, and swampy ground. We are likely to think that the ideas behind these maxims are much more modern. If tourists would take them to heart there would be much less aftermath of disease following vacations.

It was especially exposure to the heat and the sunlight that the Romans insisted on as most enervating. There is probably nothing that lowers resistive vitality and lays one open to the influence of disease like exhausting exposure to the sun. In recent years so much has been said of the benefit of sunlight that we sometimes forget that, like every other good thing in excess, it may be intensely harmful. Exposure to the sun is likely to be especially baneful if its effects are not neutralized by longer hours than usual of restful sleep. It is this especially that travelers are likely to miss. Most people do not sleep so well away from home as at home. Often the feeling that one is losing the precious hours of vacation is allowed to shorten the time spent in bed. For the very young this policy may not prove harmful, though it must not be forgotten that it is among them that we most frequently see the sad results of vacations supposed to be taken for health improvement. Among the middle aged, however, there is no doubt that unless taken with some of the Roman maxims in mind, vacations may well prove more harmful than beneficial.

EXPLOITING THE TUBERCULOUS.

The latest scheme for utilizing the physician as a decoy in a "hold-up game," in which wealthy tuberculous patients or their friends play the part of the unwilling, and apparently unconscious, victims, hails from Arizona. Located at Tucson, Ariz., there is a stock corporation which rejoices in the euphonious, if somewhat enigmatic, name of "The Southwestern Extraforaneous Company." Now extraforaneous—which is classed by the Standard Dictionary as a "rare" word—means "situated outside the door"; in other words, out-of-doors. The name, in brief, is that of a sanitarium for the tuberculous. As the circular says, to "attract moneyed consumptives" it is desirable to have physicians as agents and to secure their services "it is necessary that they be stockholders of the company." But—and here is the kernel of the nut—in addition to receiving dividends as stockholders, each "agent physician receives a liberal commission based on the receipts from the patients sent by him." "Agent physician," by the way, is a good term—one tending to promote a feeling of self-respect! The great advantage to be derived from this system of secret commissions is the fact that the "agent physician will also be careful to send only those patients who are wealthy . . . as otherwise he would reduce his commissions and dividend on his stock." But the dividends, apparently, are but an incident—the drawing card is the commission; for the circular points out that "in view of the fact that we pay a liberal commission based on the receipts from the patients sent us, we feel that our agents should not look too much to dividends." As the company is capitalized at $1,000,000 this suggestion to the stockholders is possibly to forestall disappointment. The pamphlet referred to is entitled "Physician's Edition." As in it the statement is made that "in the successful treatment of consumptives the patient must be kept in a . . . contented state," it is assumed that the descriptive circulars sent to prospective patients do not include a copy of the "Physician's Edition." It would hardly be conducive to "a contented state" for even the wealthiest of consumptives to know that a certain percentage of the money he was paying for board and lodging at the Southwestern Extraforaneous Company's sanitarium was surreptitiously being forwarded to his family physician in the form of commissions.

EXAMINATION OF THE DIASTASE FERMENTS AND THE VALUE OF THE COUNCIL'S WORK.

The report of an examination by the Council on Pharmacy and Chemistry of various diastase ferments, which appears[1] in this issue, calls attention to a fact too often overlooked or forgotten. We refer to the great value to physicians of an impartial examining body for determining the efficiency of the various therapeutic agencies offered them by manufacturers. There was a time when the medical profession had to get its scientific reports on the physiologic or chemical value of a proprietary product from the respective makers of such products. That in such reports, coming even from firms of the highest standing, the personal equation was likely to play an undue part was, in the nature of the case, unavoidable. It is to be expected that manufacturers marketing a preparation will naturally apply such tests for determining its value as will place their products in the most favorable light. That time is past; the medical profession is to be congratulated on having, in the Council on Pharmacy and Chemistry, a body under whose direction the various preparations put on the market may be examined scientifically and without commercial bias. Probably no class of medicinal agents has received so much commercial exploitation as that comprising the digestive ferments; and of this class the diastasic products have been the favorite. As to the questionable need or value of the digestive ferments in general this examination has nothing to do. Only this fact is considered: Do the starch converters really do the amount of work claimed for them? The examination shows that "the digestive values are all lower than claimed." Particularly was this found to be true in the case of Taka Diastase, a product which has probably been more extensively advertised than any similar preparation that was ever offered to physicians. In its liquid form this digestant was found to lose strength very rapidly, and, whatever may be its converting power when sent from the factory, after being on the druggists' shelves for a short time it becomes practically inert. The solid preparation, also, was "far from satisfactory." The examination, in short, simply confirms the statement so often iterated and reiterated in these columns: Accept with large mental reservations the claims made by manufacturers for the various products in which they hold proprietorship.

Medical News

DISTRICT OF COLUMBIA.

Must Stamp Oleomargarin.—Secretary of Agriculture Wilson has made a ruling in which he declares the regulations recently promulgated, to become effective July 1, requiring the stamp of government inspection on oleomargarin, shall stand as made. This decision upholds the contention of the dairy interests in their controversy with the oleomargarin manufacturers.

To Prevent Escape of Patients.—The board of charities has forwarded a communication to the commissioners favoring more stringent rules governing the establishment and maintenance of private hospitals and asylums in the District in order to prevent the escape of patients from such institutions while under treatment. Reference is made to several fatalities due to the negligence of attendants.

Personal.—Dickinson College has conferred the degree of LL.D. on Dr. Hugh M. Smith, deputy commissioner of fisheries.——Dr. Joseph Tabor Johnson has been elected president of the Washington Country Club.——Dr. P. G. Smith has been appointed superintendent, and Dr. J. M. Pearson resident physician, of the new tuberculosis hospital recently erected at Georgia Avenue N. W. at a cost of $100,000.

Health Report.—According to the health and mortality record for the week ended June 20, there were 116 deaths and 116 births in the District. Of the deaths, 70 were white and 46 colored. Of the births, 82 were white and 34 colored. The excessive heat resulted in doubling the infant mortality as compared with the previous week. The number of diphtheria cases was increased, there being 11 under treatment. Ten new cases of typhoid brought the list up to 79, and 8 new cases of measles and 9 chickenpox were reported.

ILLINOIS.

Smallpox.—There have been three additional cases of smallpox discovered at the Rock Island County farm, but none of the patients is seriously ill.

Society Organized.—The physicians of LaSalle and Peru, on June 23 met and organized the Twin City Medical Society, a branch of the LaSalle County Medical Society. The following officers were elected: President, Dr. B. J. Nauman, Peru, and secretary, Dr. Frederick A. Guthrie, LaSalle.

Personal.—Dr. S. Walter Ransom has been appointed associate professor of anatomy in the Northwestern University Medical School, Chicago.——Dr. Don A. Vanderhoof has returned from Vienna and located with Dr. Horace M. Starkey in Rockford.——Dr. James A. Rutledge, Elgin, has been made a member of the board of directors of Modern Woodmen of America.

Chicago.

Election.—At the annual meeting of the South Side Medical Society, June 19, Dr. Edwin B. Tuteur was elected president and Dr. F. Gurney Stubbs secretary.

Personal.—Drs. Alfred D. Kohn and Alexander L. Blackwood have been appointed members of the board of education. ——Dr. John B. Murphy and family leave for Europe July 12.

Unlicensed Practitioners Fined.—Mrs. L. Brunswick, Mrs. F. Kantz, Hanna K. Blomberg and H. H. Hill, charged with practicing medicine without licenses, are said to have been found guilty and fined $100 and costs each. None of the defendants appeared in court.

---

[1] Pharmacology Department, p. 140.

New Dispensary.—The Northwestern University Medical School is about to erect a dispensary on property on Calumet Avenue, north of Mercy Hospital, which was acquired by Dr. John B. Murphy for the institution and was conveyed by him to the university, June 26, for a consideration of $7,801.

Hospital News.—Jackson Park Sanitarium was opened for the season June 27. Addresses were made by Dr. W. Augustus Evans, commissioner of health, Dr. Alfred C. Cotton, superintendent of the sanitarium, and others.——The twenty-second season of the Daily News Fresh Air Fund Sanitarium, Lincoln Park, began June 29.——Iroquois Memorial Emergency Station No. 1 is to be opened at 87 Market Street by the Iroquois Memorial Association. The association is prepared to spend $25,000 in equipping the building, and it will be provided with everything deemed necessary. The first floor is to be an ambulance station: the second a dispensary. and on the third floor will be the operating room and beds for patients.

Danger from Flies.—The weekly bulletin warns that the common house fly should be kept out of homes and away from food. and the chances of avoiding diarrheal disturbances and typhoid fever this summer will be much better. All cases of typhoid fever and most cases of diarrheal disease are due to infection. The infection is present in human discharges; from these discharges it is conveyed into the mouths of others in several ways; but the common house fly is the commonest and most mischievous of all carriers. The greatest prevalence of the diarrheal diseases corresponds with the greatest prevalence of flies. Most typhoid infections also occur at this time. Flies may also be the conveyors of scarlet fever. diphtheria, tuberculosis and other infectious diseases. They walk over or feast on the infectious matter in a sick room and then go to a neighboring home and find their way to the food of other persons.

INDIANA.

Personal.—Dr. Charles C. Terry and family. South Bend, sailed for the Mediterranean June 20.——Dr. Charles K. Bruner. Greenfield. has been appointed local surgeon for the T. H., I. & E. Railway.——Dr. and Mrs. Xene Smith. Huntington, have returned from abroad.——Dr. E. Oscar Lindermuth, Indianapolis. is said to be ill with smallpox in the isolation hospital.

State Society Meeting.—At the fifty-ninth annual meeting of the Indiana State Medical Association. held in French Lick Springs, June 18 and 19. the following officers were elected: President, Dr. George D. Kahlo, French Lick; vice-presidents, Drs. Edward D. Freeman, Osgood: Charles H. McCully, Logansport, and Charles Chittick, Frankfort; secretary, Dr. Frederic C. Heath. Indianapolis (re-elected); treasurer, Dr. Albert E. Bulson, Jr.. Fort Wayne. and delegates to the American Medical Association, Drs. William N. Wishard, Indianapolis; Edwin Walker, Evansville: Harry C. Sharp, Jeffersonville, and George W. Thompson, Winamac.

MARYLAND.

Baltimore.

Quarantine Raised.—The quarantine of the smallpox suspects at Poplar Heights, in the suburbs of Baltimore, has been raised.

Woods Club.—The members of the medical staff of the University Hospital have formed an out-of-door recreation club to be known as the "Woods Club." The requirement for membership is a "sincere love for the out of doors and old clothes."

New Infectious Diseases Hospital Ready.—It is announced that the new hospital for infectious diseases is completed and ready for occupancy. It is a simple one-story building. with large porches at either end. There are two wards for white and two for colored patients, accommodating thirty-two in all. There are four rooms for private cases. The building is on the ground of the City Almshouse.

Vital Statistics for June.—During the month there were 266 deaths of children under 5 years of age, 32.6 per cent. There were 86 deaths from intestinal diseases in children under 2 years of age. The total number of deaths was 816, and there were 735 births. Eighty persons were bitten by dogs; there were 20 fatal accidents; 11 persons attempted suicide, 2 were successful.

Personal.—Dr. James H. Bay, of the house staff of University Hospital, was operated on for appendicitis, June 27.——Dr. Daniel Z. Dunoth will spend the summer at White Sulphur Springs Va.——Dr. Leonard M. C. Parker has gone to Europe.——Dr. L. McLane Tiffany is at Magnolia. Mass.——Dr. H. Barton. Jr.. will spend the rest of the summer at Newport.——Dr. Ira Remsen is at Prout's Neck. Maine.——Drs. Charles O'Donovan and G. Milton Linthicum have recently been added to the faculty of Baltimore Medical College.

New Buildings for Baltimore Medical College.—The Baltimore Medical College will shortly erect a large library and laboratory building on ground purchased last year. There are to be three lecture halls. with a seating capacity of 200 each. also chemical. physiologic, pathologic and physical laboratories and lecture and library rooms for the Baltimore law school. which will be affiliated with the college. The building will be of brick. four stories high. and will cost about $50.000. The members of the building committee are: Profs. G. Milton Linthicum. William E. Moseley, James M. H. Rowland and Samuel K. Merrick.

MASSACHUSETTS.

Hospital Acquires Property.—The Massachusetts General Hospital has acquired 595 square feet of land adjoining the hospital grounds.

Commencement.—At the annual commencement of Harvard Medical School. a class of 64 was graduated. and 12 members of the class received the degree of M.D. *cum laude*. The honorary degree of D.Sc., was conferred on Col. William C. Gorgas. Medical Corps. U. S. Army.

Medical Student Drowned.—The body of Reginald Sears James, a senior student in Harvard Medical School. who mysteriously disappeared several days before. was found in the Charles River May 27, and it is believed that while suffering from melancholia caused by worry over his studies. he committed suicide.

Floating Hospital.—The first trip of the Boston Floating Hospital was made July 1. The boat will make daily trips. including Sundays. up to September 15. During last season the total number of patients on all trips was 2.639, and there were 366 permanent patients. who stayed in the hospital an average of 70 days each.

Communicable Diseases.—There is said to be a great increase in typhoid fever in Fitchburg. where nine cases have been reported recently.——The Board of Health. Worcester, has traced the origin of thirteen cases of diphtheria to the distribution of milk by one dealer in Quinsigamond.——Diphtheria is reported still to be prevalent in Ware.

Reception to Revision Committee.—On May 23. the New England Branch of the American Pharmaceutical Association and the Boston Association of Retail Druggists tendered a reception to the revision committee of the U. S. Pharmacopeia. at which a number of prominent physicians of Boston were present as guests. Mention was made at this dinner of the great friendliness now existing between the professions of medicine and pharmacy.

Tuberculosis Camps.—The open-air camp provided by the Springfield Society for the Prevention of Tuberculosis is now arranged and in readiness for the care of patients.——Ground has been broken for the tuberculosis camp in Cambridge. for which an appropriation of $20.000 was recently made. The building will be one story in height. with two wings. each 25x50 feet, and the front will be made almost entirely of glass. Primarily this institution will be a day camp. in which patients will be instructed in hygiene and will receive other treatment. Later it is planned to build a hospital for the care of contagious diseases.

MICHIGAN.

Communicable Diseases.—There is said to be an epidemic of diphtheria of mild type in Holland.——At East Fremont there are said to be 10 or 12 cases of smallpox of mild type.

Degrees Conferred.—The University of Michigan. at its recent commencement, June 18, conferred the degree of M.A. on Dr. Walter Courtney. Brainerd. Minn., chief surgeon of the Northern Pacific Railroad; the degree of D.Sc. on Dr. Franklin P. Mall of Johns Hopkins University. and the degree of D.Sc.. on Dr. William J. Mayo, Rochester. Minn. All thus honored were members of the medical class of 1883.

Personal.—Dr. Oscar C. Breitenbach. Escanaba. was elected president of the Lake Michigan Water Commission, May 27.——Dr. H. F. Thomas, surgeon, and J. N. Holcomb. assistant surgeon of the Soldiers' Home, Grand Rapids, have resigned.——Dr. Felix J. Przybylowski has succeeded Dr. Zigismund L.

Kadlubowski as city physician of Detroit.——Dr. James C. Johnson, city physician of Adrian, has resigned.——At the May meeting of the Gratiot County Medical Association, Dr. Stiles Kennedy, St. Louis, was the guest of honor, and was presented with a silver loving-cup, suitably inscribed.

MISSOURI.

Personal.—Dr. William C. Goodwin, Odessa, the oldest practitioner of Lafayette County, was the guest of honor at the May meeting of the Lafayette County Medical Society.——Dr. Herman E. Pearse, Kansas City, has sailed from Montreal for Europe.——Dr. Oscar M. Long, Harrisburg, who is alleged to have shot and seriously wounded a clergyman, December 16, after an altercation relative to the local option campaign, is said to have been found guilty at Columbia, June 23, and fined $100 and costs.

State Society Meeting.—At the fifty-first annual meeting of the Missouri State Medical Association, held in Springfield May 19-21, the following officers were elected: Dr. Alonzo R. Kieffer, St. Louis, president; Drs. Dexter B. Farnsworth, Springfield; William J. Frick, Kansas City; Joseph B. Norman, California; Charles H. Dixon, Holliday, and Marshall A. Smith, Gallatin, vice-presidents; Dr. Andrew W. McAlester, Jr., Kansas City, secretary, and Dr. J. Franklin Welch, Salisbury, treasurer. Dr. Robert H. Goodier, Hannibal, was elected orator on medicine, and Dr. Frank J. Lutz, St. Louis, orator on surgery. Dr. Elisha E. Gilmore, Adrian, was selected as chairman of the medical section; Dr. Franklin E. Murphy, Kansas City, vice-chairman, and Dr. William R. Patterson, Tipton, secretary; Dr. Paul Y. Tupper, St. Louis, chairman of the surgical section, and Dr. Willard Bartlett, St. Louis, secretary. A committee composed of Drs. Thompson, Kansas City, Tipton McLemore, Nevada, and Mitchell C. Shelton, Joplin, was appointed to organize an eye, ear and throat section of the association.

NEW YORK.

Personal.—Dr. Robert F. Sheehan, Buffalo, has been appointed a food inspector of the department of health.——Dr. De Witt Green, Buffalo, has resigned as district physician of the department of health.

University of Buffalo Acquires Property.—An arrangement has recently been effected by means of which the University of Buffalo has acquired from Erie County, New York, one hundred and four acres of land to be used for university purposes. The tract is splendidly located at the summit of the limestone ridge at the northern edge of the city, adjacent to the Country Club. The Medical Department of the University of Buffalo was founded in 1846, and three other professional schools have been organized since that time. The need for an academic department has long been felt and its organization now seems in a fair way to be accomplished. The land here mentioned will be devoted to that purpose.

NORTH CAROLINA.

State Board of Examiners Elected.—The following were elected by the state society as the board of medical examiners of the State of North Carolina for six years: Drs. James L. Nicholson, Richlands; Henry H. Dodson, Greensboro; Lewis B. McBrayer, Asheville; William W. Mackenzie, Salisbury; Benjamin K. Hays, Oxford; John C. Rodman, Washington, and John Bynum, Winston-Salem.

State Society Meeting.—At the fifty-fifth annual meeting of the Medical Society of the State of North Carolina, held in Winston-Salem June 16-18, the following officers were elected: President, Dr. Jacob F. Highsmith, Fayetteville, and vice-presidents, Drs. Chalmers M. Poole, Salisbury, and Daniel A. Dees, Bayboro. The society passed a resolution advising the board of examiners to revoke the license of any practicing physician who is found violating the prohibition law by promiscuously writing prescriptions for whisky. This is the result of the petition presented by the ministerial association of several towns of the state.

PENNSYLVANIA.

Bequest.—The will of the late John B. Roach bequeaths $5,000 in trust to the Chester Hospital.

Cocain Sellers Sentenced.—Eugene Fairfax and Lizzie Acy, colored, who were arrested by the city police of Harrisburg as the ring leaders in the cocain traffic, were fined and sentenced to six months in jail June 15.

Free Antitoxin.—According to a report of State Health Commissioner Dr. Dixon, from October, 1905, to December, 1907, the state distributed antitoxin for the treatment of 8,833 cases of diphtheria. Of this number, 7,926 patients were saved, only 807 cases resulting fatally. In addition, the state furnished antitoxin to immunize 6,184 persons. Of these, all but 53 were protected against the disease, and of the 53 who did contract the disease only 5 succumbed. The total cost of the antitoxin supplied these 15,017 persons was $40,826.25.

Philadelphia.

Commencement.—The annual commencement exercises of the University of Pennsylvania Department of Medicine were held June 19. The annual address to the graduating class was delivered by Dr. Edgar Smith, vice-provost of the university. A class of 143 was graduated.

Public Baths Opened.—On account of the excessive heat during the past week, the city's public baths were opened June 24. One new bath has been added, making a total of 19. The baths will remain open daily from 5 a. m. to 9 p. m., except Sunday, when they will close at 9 a. m.

Health Report.—The total number of deaths reported for the week ended June 27 was 500, including 274 males and 226 females, an increase of 97 over the previous week and of 51 over the corresponding week of last year. The principal causes of death were: Typhoid fever, 6; measles, 8; pertussis, 6; consumption, 53; cancer, 33; apoplexy, 15; heart disease, 33; acute respiratory disease, 37; enteritis, 63; hepatic cirrhosis, 5; appendicitis, 2; Bright's disease, 31; premature birth, 14; congenital debility, 13; suicide, 4; accidents, 15, and marasmus, 21. There were 115 cases of contagious diseases reported, with 9 deaths, as compared with 139 cases and 16 deaths in the preceding week.

Drop in Typhoid.—The lowest typhoid fever record since 1897 was reached during the first week of June. Only 25 cases were reported in that period, and this is the smallest number reported in any week in the history of the health department. Dr. A. C. Abbott, chief, stated that the reported cases in any one week since February 22 has not reached 100, and since May 16 the number has been below 50. In previous years the early spring weekly average was from 200 to 350 new cases. From January, 1908, to the present time there has been a decrease in typhoid fever of 66 per cent. as compared with the same period of last year. The extension of the filtered water area, it is believed, has influenced this decrease, but the number of cases in the unfiltered districts also shows a proportionate decrease.

Personal.—Dr. G. Oram Ring has returned from Mexico.——Dr. Morris B. Miller sailed for Europe June 12.——Dr. Ward Brinton had the degree of M.A. conferred on him by Washington and Jefferson College at the annual commencement exercises June 16.——Drs. Wharton Sinkler, Horatio C. Wood, John Marshall, Benjamin F. Stahl, William S. Wadsworth and Roland G. Curtin were elected to the board of directors of the general alumni association of the University of Pennsylvania, Department of Medicine, at the annual meeting June 16.——Dr. John M. Swan has been appointed secretary for the United States of the Section in Tropical Medicine of the fifth Pan-American Medical Congress.——Drs. Peter N. K. Schwenk, David G. Metheny, Thomas S. K. Morton, Morris Longstreth and Elwood Matlack have sailed for Europe.——Dr. William L. Rodman has resigned the chair of surgery in the Woman's Medical College of Pennsylvania, the resignation to take effect at once.

WASHINGTON.

Garbage Collection.—Seattle has appropriated $65,000 for furnishing a garbage collection and incinerating system to take the place of the personal collection of garbage by private individuals.

Communicable Diseases.—A case of smallpox is reported on board the U. S. steamship *Kentucky* at Bremerton.—At Prosser ten families are quarantined on account of smallpox.——A large number of cases of diphtheria is reported at Rock Cut and in Stevens County. For a time it was confined to Indians, but is now spreading among the white settlers.

Milk Statistics to Be Published.—The daily newspapers of Seattle will be furnished with full data relative to dairies disposing of milk in the city, the product of which falls below standard of the ordinance. A list will also be published of the establishments maintaining a high standard so that the public may have information on this most important subject.

Alleged Illegal Practitioner Discharged.—In the case of Mrs. Linda B. Hazard, Seattle, charged with practicing medicine without a license, the charge being based on the fact that Mrs. Hazard displayed a sign, "Doctor," on her door contrary to the statute governing and defining physicians and surgeons, the court held that section of the statute to be invalid, as it infringes on the personal liberties of the individual. There was no evidence that Mrs. Hazard wrote prescriptions or practiced medicine.

GENERAL.

Medical Examiners Meet.—At the ninth annual meeting of the American Association of Medical Examiners, Dr. Frank E. Allard, Boston, was elected president; Drs. Liston H. Montgomery, Chicago; William J. Means, Columbus, Ohio, and E. Olin Kinne, Syracuse, N. Y., vice-presidents, and J. C. Moynihan, New York City, secretary-treasurer (re-elected).

Officers of Pension Examining Surgeons.—At the annual meeting of the National Association of United States Pension Examining Surgeons, held in Chicago, June 1, the following officers were elected: President, Dr. Henry B. Walter, Harrisburg, Pa.; vice-presidents, Drs. Allen W. Gray, Chicago; James B. Duncan, Bedford, Ind.; Edwin Bentley, Little Rock, Ark., and Franklin R. Garlock, Racine, Wis., vice-presidents; Dr. Philip Y. Eisenberg, Norristown, Pa., secretary, and Dr. Charles H. Glidden, Little Falls, N. Y., treasurer.

Lake Michigan Water Commission.—The Lake Michigan Water Commission was organized recently at Grand Rapids for the purpose of the prevention of pollution of Lake Michigan by legislation prohibiting the flow of sewage into the lake. The commission is composed of surgeons from Michigan, Wisconsin, and Illinois, and the War Department, and Public Health and Marine-Hospital Service. The following plans were agreed on at the recent annual meeting of the commission to further their work: To gather further information as to the existing conditions of the water supply; to study conditions from a hygienic standpoint; to discover whether or not Lake Michigan is polluted, with special reference to conditions along the shores; to analyze the present condition of the lake water with relation to depth; to study the problem of non-sewered towns, both those using lake water and those getting their supply from wells, and, finally, the pollution of streams emptying into the lake.

Fourth Congress of the French-Speaking Physicians of North America.—This medical congress is to be one of the features of the widely advertised celebration of the three hundredth anniversary of the founding of the city of Quebec. The congress will convene July 20 to 22, with Prof. A. Simard in the chair. Dr. S. A. Knopf, New York, has been appointed one of the twelve honorary presidents of the congress, the only one from this side the Canada boundary, with Pozzi and Triboulet, of Paris. The subjects to be discussed are: "Hygiene in Education;" "Infection of the Biliary Passages," and "Tuberculosis of the Kidney." The *Bulletin Médical de Québec* states that the Canadian railroads and steamboat lines allow half rates between July 18 and August 3 to all who apply for a ticket to Quebec, and the railroads in Eastern New England are said to have agreed to a similar reduction. Lodgings have been reserved for members of the congress at from $2 to $5 a day, or in the "Tented City" for less. The St. Louis Club will also throw open its doors to the members during the anniversary festivities. Dr. W. Verge is president of the committee on accommodations. Besides the congress badge the committee expects to present each member with a souvenir plaque. The meetings will be held in the historic Laval University. Dr. Knopf is to deliver an address entitled, "Le Sanatorium, le Dispensaire et l'Hôpital Spécial pour le Traitement des Tuberculeux." A notable delegation from France will be present at the congress.

FOREIGN.

Hernia Institute at Milan.—The Bassini Institute at Milan, which is devoted exclusively to the free treatment of hernia in the poor, has recently received some comparatively large donations.

The International Bureau of Public Health.—The Italian government has appropriated $3,000 as its annual share in the expenses of the central office, which the International Public Health Conference last December agreed to organize, with headquarters at Paris.

Cannizzaro Chemistry Prize.—The Academy of Sciences at Rome, Italy, announces the endowment of a prize of $2,000 to be awarded perpetually every two years for the best work on pure and applied chemistry with special regard to physical and general chemistry. The prize is open to the world.

Sixteenth International Medical Congress.—A number of copies of the preliminary program, regulations, application blanks and various notices in regard to the Sixteenth International Medical Congress have been received at this office and are at the disposal of those interested. As already announced, this congress is to be held at Budapest, Aug. 29, 1909, and extensive preparations are being made to insure its success. Dr. J. H. Musser, 1929 Chestnut Street, Philadelphia, is the chairman of the national committee for the United States, Landouzy for France, Waldeyer for Germany, Pavy for Great Britain and Baccelli for Italy. An international prize of $200 has been offered by the Hungarian government for the best work on the Etiology of Trachoma, manuscript or published for the first time in 1907 or 1908, in any of the congress languages. Works sent in to compete for the prize must be in the hands of the minister of the interior by Dec. 31, 1908. (Address Belügyministerium, Budapest, Hungary.) The International Committe of Travel for Medical Study will also hold its general assembly at Budapest during the congress. There are to be 21 sections, with a subsection for orthopedics. The section for otology is practically identical with the Eighth International Congress for Otology. The congress fee of $5 may be sent to the treasurer of the congress. (Address M. le Trésorier du XVIe Congrès International de Médecine, Esterhazy-utcza 7. Budapest VIII.) The membership of the American committee was given in THE JOURNAL, June 13, page 2008, with other details in respect to the congress.

Plague in South America.—Consul Manning reports that the presence of bubonic plague in La Guaira and other ports of Venezuela has caused a general awakening in Cartagena to the necessity of proper precautions to prevent introduction of the disease. With this object the authorities of Cartagena and the commercial houses have taken up the cause of sanitation and are acting as rapidly and with as much vigor as possible. Under the general direction of the sanitary inspector of ports the municipality has organized various commissions, charged with the carrying out of measures. A sanitary police corps has been organized, house-to-house inspection is being made, and all refuse and trash are carted away and destroyed. A temporary garbage crematory has been erected, where this class of waste from the city is being burned. The instructions to the sanitary police are being carried out as fully as possible. Lazarettoes will be provided outside the zone of danger from the infection reaching the city to which any suspicious cases are to be taken, should such appear, and it is the intention of the health authorities to isolate any future cases of yellow fever or smallpox. Of the former, no cases have appeared here since June, 1907, and no smallpox has been reported in the city since then. For further protection against plague a campaign against rats, mice and bats will be necessary. The latter are very plentiful, inhabiting the underground passages of the old forts Castillo de San Felipe, San Sebastian and others, as well as unoccupied houses. With a view to the destruction of rodents the use of rat traps, rat poisons and other plans are being adopted as rapidly as possible.

BERLIN LETTER.

(From Our Regular Correspondent.)

BERLIN, June 20, 1908.

Economic Position of German Physicians.

Since I gave, in my former letter, an account of the preliminary and postgraduate education of physicians in Germany, I will add some observations on the important factor, in the professional life of medical men, of their economic mode of life. For the last decade there has been much complaint over the material position of German physicians. In the first place it must be borne in mind that from various causes all of the learned professions in Germany (and possibly in many other countries) have, as the saying goes here, not been lying on beds of roses, and the medical profession is no exception. One common cause for the material depression of all the learned professions is their overcrowding. The tendency to enter the academic callings has been a strong one for decades in Germany, and as the increase of population does not keep pace with it, the prospects for adequately supporting the great mass of the members of the learned professions have been correspondingly poorer.

In order to appreciate these conditions in the medical profession, it is only necessary to point out, that in the year 1897, according to the Imperial Medical Calendar, there were in the German empire 4.75 physicians for 10,000 inhabitants. In 1907, on the other hand, there were 5.25. In absolute figures there had been added more than 6,000 to the number of physicians in Germany. Aside from the overcrowding of the profession, two factors have been of special importance in producing a deterioration of the economic condition: social legislation, and the continuous spread of quackery. Since 1883 the great mass of the working population have been insured by an imperial law against sickness, accidents, and disability. The insurance against sickness is of most importance to the medical profession. By this law a large portion of the population of Germany is excluded from the private practice of physicians; the insured have a right to free medical treatment and the physicians are paid by the local medical insurance clubs, the *Krankenkassen*. The economic significance of this organization for the medical profession may be shown by the following figures: In 1906 there were about 23,000 such societies, which included 11,500,000 members. The number of cases of illness which involved inability to labor amounted to 4,500,000, with about 87,500,000 days of illness. The regular income of all the societies amounted to 293,000,000 marks ($70,320,000) the regular expenses, so far as concerns the cost of disease, were 241,000,000 marks ($57,840,000). Of these expenses of sickness 57,250,000 marks ($8,587,500) paid the fees of physicians. From these figures it may easily be understood what a powerful factor the insurance clubs are in affecting the economic situation of German physicians and also to what extent the German physician must be dependent on the insurance organization. In fact this dependency became especially acute in the first year of the social legislation, especially from an ethical standpoint, inasmuch as the managers, being aware of their power, made their right of mastery effective and looked on the physicians as their hirelings. In their efforts to obtain positions in the lodges physicians humbled themselves in an unworthy manner. Competition developed among them, from which corruption was not lacking.

As usually happens, every extreme finally provokes a reaction, and so the evil conditions described led to a combination among the physicians for mutual assistance which had for its aim to shake off the yoke imposed on them by the managers. In Berlin an agitation took its rise which had for its aim the introduction of the so-called "free choice of physicians" for all the sick benefit societies. While formerly each had a number of permanently employed, so-called "fixed" physicians, who furnished medical treatment to the sick members for a definite yearly salary, and who were appointed by the management, it was proposed that all the physicians of a city, under certain conditions, should be permitted to participate in the treatment of all the members of the society. The funds which were at the disposal of each society for the treatment of the sick (limited in proportion to the revenue) should be divided among all the physicians who had treated the sick, according to a definite uniform tariff. This proposal, which makes the physicians independent of the management and removes the monopoly of the permanently appointed "insurance physicians" in favor of the entire medical profession, has won the sympathies of the great majority of medical men. Most German physicians are supporters of the so-called "free choice of physicians." The opponents among medical men are naturally those who are in possession of the fixed medical insurance positions, while outside the profession the opposition is greatest from the directors of the insurance societies. The latter are fighting the "free choice of physician" most vigorously under the pretext that under this régime the cost of treating the sick would be too high, both in itself and in relation to the funds set apart for the purpose. The chief objection, however, is the unacknowledged motive that under the "free choice of physicians," medical men would be less under the control of the directors of the insurance societies.

In this struggle there have been severe conflicts between the physicians and the societies. The entire medical profession of one city were excluded from all part in the treatment of the members of the society, and on the other hand, the physicians of another city struck and refused to treat the members. The government has been obliged to intervene repeatedly; lawsuits have been instituted, etc. In view of this continuous strife from which both parties have suffered, it must be the endeavor of the government to find some means of settlement. The physicians some years ago organized themselves into the so-called Leipsic League for the Protection of the Economic Interests of Physicians. This embraced in 1907 about 20,000 physicians, or two-thirds of the entire German medical profession. The members of this association have of late years at their medical meetings repeatedly passed resolutions in which the legal authorization of the "free choice of physicians" was demanded, and it seems impossible that this demand shall be ignored much longer. This demand is now being pressed the more earnestly by physicians because by the contemplated reform of the sick insurance legislation the number of those who belong to the *Krankenkassen* will be very considerably increased. Under the former provision of the law those must insure themselves against sickness who possess an annual income not above 2,000 marks ($480), the proposed law will include those whose income is not above 3,000 marks ($750). At present 36 per cent. of the inhabitants belong to the insurance societies, but it has been estimated that in the kingdom of Saxony after the innovation just mentioned goes into effect, 92 per cent. of the entire populace will be members. In this way the free private practice of the physician will be still more contracted than heretofore, and the necessity of physicians securing conditions as favorable as possible for the treatment of the sick in the *Krankenkassen* is so much the more pressing. A conference has been called by the Imperial Office of the Interior for June 11, at which the question of the free choice of physicians is to be discussed by the supporters of both views with the participation of the representatives of the government. With reference to the results of this conference I will write later.

LONDON LETTER.

(From Our Regular Correspondent.)

London, June 20, 1908.

Coroner Troutbeck and the Profession.

The conflict between Coroner Troutbeck and the medical profession described in the last letter is attracting widespread attention, both in medical and lay circles. In the columns of the *Times* the coroner and Sir Victor Horsley wage an acrimonious controversy. Mr. Troutbeck's view that if a patient dies during or after an operation the surgeon should be held responsible until he has cleared himself before a coroner's jury is strongly repudiated by the profession. A coroner's court is no fit tribunal to decide whether an operation should have been performed or not, or to criticize the skill of the operator. If a surgeon in the often difficult and delicate problem of deciding whether or not an operation is desirable is to have the possibility confronting him of having his action reviewed by such an incompetent tribunal his judgment would be disturbed, and in desperate cases patients would be liable to lose the possibility of benefit from operation. Mr. Troutbeck holds that if a death is accelerated by an operation that fact brings it within the scope of the Coroner's Act which requires that when a person is reasonably suspected of dying a violent or unnatural death an inquest should be held. But in the *Times* Dr. Shearer very well argues that a death from disease under treatment *secundum artem* is not *contra naturam*. Further, if an inquest should be held on a patient who dies after operation, for the same reason an inquest ought to be held on a patient who dies under medical treatment, for there is the same possibility that the treatment may have accelerated death. The whole question, which is of such fundamental importance to the profession, is under consideration by the British Medical Association.

A Notable Medical Centenarian.

On July 1, Sir Henry Alfred Pitman, for over thirty years registrar of the Royal College of Physicians, will attain his hundredth birthday. To mark the event some of his old professional friends will visit his residence at Enfield and present him with a piece of plate. Despite his age, Sir Henry enjoys excellent health; in fact the only defect from which he suffers is impaired eyesight. When in practice he spurned a carriage and visited his patients on foot.

Healthy London.

During the third week in June the death rate in London was the lowest on record. It was only 10.8 per 1,000. The rates of the previous weeks were 11. 11.6 and 11.7.

The Entente Médicale.

The *entente cordiale* between England and France in recent years has had as one of its manifestations more intimate relations between the medical professions of the two countries, which has taken as one of its forms visits in a body of English physicians to Paris and of French physicians to London. A short time ago Sir Dyce Duckworth delivered a lecture in Paris to the Faculty of Medicine. Now in return Professor Raymond, the successor of Charcot at the famous Salpêtrière Hospital will deliver a lecture at the Royal College of Physicians on *Les Maladies dites Familiales*. He will also hold a clinic at Guy's Hospital, where he will demonstrate in two or three nervous cases the methods he employs at the Salpêtrière.

Pharmacology

THE BROADER AIMS OF THE COUNCIL ON PHARMACY AND CHEMISTRY.

TORALD SOLLMANN, M.D.
Member of the Council, Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University.
CLEVELAND, OHIO.

(*Continued from page 52.*)

XVI. PROPRIETARY RIGHTS.

It is almost useless to discuss the purely academic question, whether the inventor of a medicinal agent should hold his discovery as a monopoly, or whether he should follow the example of the medical profession and renounce personal pecuniary reward. We may each have our personal opinions, but the fact remains that the chemical or pharmaceutical inventor is legally entitled to this monopoly; and he is generally disposed to insist on his legal rights. Indeed, by shrewdly utilizing certain technicalities, he can and does render this monopoly more complete and more permanent than was ever contemplated in the theory of the patent laws. The protection is so far-reaching that it checks further improvement, instead of fostering it, as theoretically it should do.

If the new remedy is really unique and valuable, if it is a genuine discovery and an advance, then it would be ungracious to begrudge the discoverer a reasonable reward in the way of protection, so long as this does not place a disproportionate burden on the public. Indeed, this proprietary protection may be to the best interest of the public, in those individual cases in which the discoverer employs a fair share of his profits in further research, to enable him to exercise and extend his inventive talent.

It is a little more irritating if the extra profit goes almost entirely to some large chemical corporation, which has forced the real discoverer to "sell out" for a mere pittance. But even in this case, there may be a fair value given in return. For instance, the expense of quickly introducing a valuable therapeutic agent is considerable, and the profits must be sufficiently large to pay for the advertisement. Right here, however, we should remember that the greatest discoveries require the smallest outlay for advertising. One of the objectionable features to proprietorship is that the users of a valuable invention must pay the cost of advertising the worthless invention.

ORIGINAL AND PSEUDO-ORIGINAL PROPRIETARIES.

On the whole, however, no one quarrels very seriously with the protection accorded to really original and valuable discoveries. It is otherwise with products which are not essentially original—and these constitute the bulk of the proprietary stock. Many "synthetics" even, are mere imitations of other successful products, and involve little more ingenuity than the placing of quinin in capsules. In some cases, all pretext of originality is dispensed with, as in the numerous proprietary hexamethylen tetramins or phenolphthaleins. One is sometimes tempted to wish that the patent laws were a little more effective in preventing this kind of discoveries. The worst examples, however, are the "proprietary mixtures."

By what right can the exploiters of Bromidia, Listerine, Glycothymoline and all the others, claim the protection due to discoverers? What is there original about these mixtures? So little that they would have no standing in the patent office, and their promoters are obliged to resort to the subterfuge of copyrighting a coined name, or to some similar expedient; or to the favorite "patent medicine" device of secrecy, partial or complete. Secrecy, in one form or another, is almost indispensable for the effective control of these specialties, which are not "discoveries" in any sense of the word.

The only legitimate claim of proprietary mixtures to protection and professional recognition would be by pharmaceutical superiority—by quality. If they really possess this superiority, it can be protected by the same methods that are used by the manufacturers of superior official products. These have not found it necessary to patent, copyright, or fancy-name their ether, or ergot, or quinin. A physician can prescribe any make of these official products which he believes superior, with very little fear that other makes will be substituted.

THE PSYCHIC VALUE OF A PROTECTED NAME.

The fact is, the manufacturers of the pharmaceutical "specialty" mixtures lay but small stress on the superior pharmaceutical quality of their goods—sometimes for good and sufficient reasons. They adopt these "protective" names for a very different reason, namely, *that they may safely make illegitimate therapeutic statements*. It is a puzzling psychologic problem, but it appears to be a fact, that it is easy to persuade the physician that the same substance acts differently when prescribed as "antikamnia" and as "acetanilidum;" while it would take much more argument to persuade him that A's make of acetanilid is superior to B's brand.

Proprietary rights are expensive luxuries to the public; some one must pay from two to ten times the ordinary profit to the manufacturer. But this is the smallest of their evils. Proprietorship, in addition to the viciousness of secrecy, always tends to extravagant therapeutic and other false claims, dangers which can only be avoided when the proprietor himself realizes the responsibilities as well as the profits of proprietorship. Otherwise, proprietary rights are inimical to the true interests of therapeutics. Proprietorship may be condoned in really new and meritorious discoveries, as a necessary and not unmixed evil; it has no excuse in imitations and mixtures. In these it is maintained merely and solely by the tolerance of physicians, who thus foster the abuses to which it gives rise.

(*To be continued.*)

DIASTASE FERMENTS.

Report of an Examination of the Diastase Ferments by the *Council on Pharmacy and Chemistry.*

A subcommittee makes the following report to the Council with the recommendation that it be published:

Among medicinal agents which may be classed as legitimate pharmaceutical preparations few are more widely advertised than are the starch-digesting ferments, the diastases. Along with a number of very good preparations there are several for which grossly exaggerated claims are made, and which are advertised to the medical profession in such a manner as to lead to distrust. Those which have merit have not always been marketed by methods which are wholly free from criticism. In several cases the claims made are more than can be substantiated by actual tests.

There has always been some obscurity in the method of reporting the digesting value of these diastases, and just what is meant by starch conversion or sugar formation is not always clear. In other words, the claims of the manufacturers are frequently stated in terms which are too general.

To be of value statements regarding the digesting power of the diastases should be based on standard and uniform methods of testing. But manufacturers have followed different methods of examination, which naturally makes a fair comparison of products difficult, and in some cases impossible, for any one not conversant with the methods of analysis. Recognizing the importance of uniformity in such work the subcommittee has had a large number of comparative tests carried out on the more important products of this class, employing several methods of analysis. In practice the diastatic action may be measured in terms of malt sugar formed from an excess of starch in a given time, or by the conversion of the starch to a point where the test with iodin shows the disappearance of the blue color, or the disappearance of all color. Results by these three methods are not directly comparable, although there must be some relation between them. Our first experiments were directed toward the clearing up of this point. These experiments were carried out largely by Mr. W. A. Johnson and the most important of them are given in detail in a paper which appears in the May number of the *Journal of the American Chemical Society*. From his numerous tests Mr. Johnson concluded that the best practical comparison may be made by carrying each digestion to the colorless end point, and in his paper certain suggestions are made as to the best methods of conducting the tests. These will be referred to below.

The following table contains the results obtained with a number of commercial products, when examined in this way, the digestions being continued through a period of ten minutes, at a thermostat temperature of 40 C. in all cases. All the products here examined came from the manufacturers, and the results were confirmed by tests on similar products bought in wholesale drug houses. The results are expressed in four ways for comparison as follows:

A.—Parts of 100 % starch digested to colorless endpoint in ten minutes.
B.—Parts of 92 % starch digested to colorless endpoint in ten minutes.
C.—Parts of 85 % starch digested to colorless end point in ten minutes.
D Parts of 85 % starch digested to loss of blue iodin reaction in ten minutes.

Trommer's Extract with Cod Liver Oil......	0.38	0.41	0.44	....

The blank spaces in the fourth column of figures indicate that no tests were satisfactorily completed here to show the conversion to loss of blue color. In fact, with highly colored mixtures this test is not as easily made as the other.

A comparison of the results given in the table with the statements which appear in the manufacturers' circulars, etc., show that the digestive values are all lower than claimed, if we base our comparison on the colorless endpoint reaction, and anhydrous starch conversion. If, however, we carry the digestion merely to the loss of blue color, which seems to be the case in some of the tests frequently cited, and employ starch with an average water content of about 15 per cent., a very different status must be reported. In this manner of reporting results five of the preparations show even more than the claimed values, but the method should not be tolerated for obvious reasons. The results actually found should always be calculated to anhydrous starch for reporting.

The discrepancies between the values claimed for Holadin, Diazyme Essence and Diazyme Glycerole and those actually found in our tests are not very great.

While one part of Holadin by the firm's method is stated to digest 135 parts of starch to the practically colorless endpoint, column C shows that by the method employed in these experiments only 120 parts of 85 per cent. starch were digested to the colorless endpoint. Similarly, while for Diazyme Essence and Diazyme Glycerole it is stated that 1 c.c. will digest 8 gm. "dry" starch to the colorless endpoint, the results given in the table above show that one part digested 6.12 parts of 100 per cent. starch to the colorless endpoint. This is equivalent to 7.14 parts 85 per cent. starch, the kind referred to by the manufacturer.

The claims made for Panase are somewhat misleading and conflicting. In a recent circular issued by the manufacturers a statement is made to the effect that one part of Panase "is capable of digesting at least 200 times its weight of starch in 10 minutes," while in another part of the same circular the complete conversion of 200 parts of starch into sugars is claimed as the work of 1 part of Panase. This claim is certainly wrong, as there is a wide difference between the two kinds of reactions. The figures in the table are sufficiently clear on this point, and suggest a proper modification of the claim to agree with the facts.

The widest discrepancy between the values as claimed by the manufacturer and those found by actual tests seems to be shown in the case of Taka Diastase. The liquid preparation has been tested a number of times in different samples and has always been found weak. Some samples, in fact, were quite inert. This ferment appears to lose strength very rapidly in solution, as the manufacturers now concede. The stability of the solid product is also far from satisfactory, and appears to be less than that of the ferment as marketed some years ago. The two samples examined recently were weak.

From a number of experiments made it appears that the stability of the diastase preparations from the pancreas is greater. In two tests of the Holadin, made some months apart, no appreciable change was noticed. The same thing is true of Panase and the earlier product of the same firm, Vera Diastase. But in the liquid form these preparations, like the Taka Diastase, seem to undergo some alteration in converting power, as the figures above, and others, suggest. Of the samples reported here the Vera Diastase essence was obtained fresh and examined at once, while the Panase Essence was on hand some time before the tests were made. According to the statement on the label the latter should be the stronger, but the reverse is the case. The Panase Essence seems to convert less than is claimed for it, while the Vera Diastase Essence converts more, if we consider 85 per cent. starch and digestion to loss of blue color merely, as satisfactory conditions of the test. It is possible that the somewhat greater age of the Panase Essence may have some bearing on the result.

The two Diazyme preparations appear to be stable, as far as practical requirements are concerned. We have examined the contents of the same bottles of these products at periods three months apart, and found no change in the starch-converting power. The claims for the numerical value of the diastatic activity and also for the stability which are made for these liquid preparations seem to be borne out by the facts as observed.

For the other liquid preparations, Maltine, Trommer's Extract, Plain and Trommer's Extract with Cod Liver Oil, there are no exact claims as to the digestive power. For Maltzyme, it is claimed that 1 gm. has the power to produce from starch, in 30 minutes, at 37.8 degrees C., 6 gm. maltose. They contain large quantities of the products of enzyme digestion, and have relatively low residual digestive value. They should be classed among the so-called medicinal foods, rather than as agents of digestion.

In the experiments carried out by Mr. Johnson, referred to above, sugar determinations were made also, and these showed a close agreement with the starch conversion, carried to the colorless endpoint. In making the tests for the sugar formation advantage was taken of the results of the other tests, and enough ferment was weighed out in each case to effect the hydrolysis of one gram of anhydrous starch to the colorless endpoint in ten minutes. A series of tests was made on each substance with the same weight of ferment and starch paste, and at the end of 10, 30, 60, 120 and 180 minutes a flask containing the mixture was removed from the thermostat, and the amount of sugar formed, calculated as maltose, was determined. On removing each flask from the thermostat further action was always checked by immediate boiling. The amount of sugar formed at the end of ten minutes was essentially the same in all the samples tested, which included the first eight of the table above. For the gram of anhydrous starch, made up to a 2 per cent. paste, the maltose formed varied between 611 and 635 milligrams, which agrees very well with the usual findings for diastase digestion, under like conditions. There are many such results in the scientific literature.

In the longer periods, however, the amount of sugar formed by the Taka-Diastase increased somewhat more rapidly than was the case with the other ferments, and the results of the determination after 180 minutes pointed to the evident conversion of some of the maltose into glucose. The mean value of the maltose formed by the other ferments in this time was about 860 milligrams, with variations from 855 to 872 milligrams, while for the Taka Diastase it was over one gram. But to secure these close results it must be remembered that very different amounts of the several ferments had to be taken at the start; that is, for the weaker digestants more, and for the stronger less was weighed out. The amounts taken varied inversely as their starch digesting activity, as shown by the first line of tests.

These relations may be illustrated by the figures in the following table, in which the first column gives the name of the substance, the second the number of milligrams actually required to convert 1 gram of starch to the colorless end-point in 10 minutes, and the third the weight of maltose formed in this time. The ferment substances were suspended in water and the proper volume was measured out to give the calculated weight. The sugar was found by titration with standard Fehling solution, and is calculated as pure maltose, proper allowance being made for the dilution of the titrated solution. The sugar amounts found under these conditions are essentially the same, but in producing the sugar 8.85 milligrams of Panase go as far as 9.79 milligrams of Holadin, 62.5 milligrams of Taka Diastase, 163.4 milligrams of the Diazyme liquids or 238.1 milligrams of the Vera Diastase Essence. In making comparisons by the table the fact must not be overlooked that the three preparations there last named are in solution, while the others are solids

TABLE OF SUGAR FORMATION IN 10 MINUTES

Column A gives the weight of ferment required in each case
Column B gives the weight of sugar formed in each case

	A	B
Panase .	8.85	622 mg
Holadin . ..	9.79	634 mg
Taka Diastase ..	62.5	611 mg.
Diazyme Essence	163.4	633 mg
Diazyme Glycerole .	163.4	635 mg
Vera Diastase Essence .	238.1	630 mg

These results, which have been obtained many times in repeating the tests, show that the starch conversion to the colorless endpoint, which is more easily and quickly carried out than is the sugar determination, gives a practically useful measure of the ferment activity, and a measure which bears a close relation to that of maltose formation. We, therefore, recommend the process for all the routine examinations of this nature which have to be made in the testing of the diastase ferments. As is explained in the article by Mr. Johnson, the process here employed was first suggested by Roberts for the examination of ferments of animal origin, and was later modified by Junck and by Francis, and applied to the ferments of vegetable origin. In our laboratory it has been submitted to critical revision with the object of securing greater accuracy through a fuller specification of details of manipulation. The most important points of the process are these, which are presented as easily and practically workable:

1. A clean grade of potato starch is thoroughly washed, first by decantation and then on a Buchner funnel. It is carefully dried at a low temperature, and finally at a higher temperature to a moisture content of about 10 per cent., the exact moisture content to be determined in a separate experiment.

2. For the actual tests about 22 grams of the starch is mixed with 100 c.c. of cold distilled water to make a uniform cream and then poured into 800 c.c. of boiling distilled water. The boiling is continued through ten minutes, and then enough water is added to make the actual starch content (anhydrous) exactly 2 per cent. by weight. For each test quantities of exactly 50 grams of the paste are weighed into a series of 250 c.c. flasks, which are clamped in a large water-bath kept at a temperature of 40 degrees.

3. The iodin test solution is made by dissolving 2 grams of iodin and 4 grams of potassium iodid in 250 c.c. of distilled water; 2 c.c. of this solution is then diluted with pure water to make 1,000 c.c.

4. In making up the diastase solution the operator must be guided by the results of a few preliminary experiments in each case. For liquid malt extracts, for example, 10 c.c. diluted to 100 c.c. will generally be a proper strength, while in the examination of the dry preparations on the market 200 to 500 milligrams, dissolved or suspended in 100 c.c. of distilled water will usually answer.

5. These solutions are used in this way: Small definite volumes of the dilutions are added to the flasks containing the starch paste in the thermostat, and with the least possible loss of time. The mixtures are well shaken. The volumes added may be as follows, but all diluted to that of the largest volume before *mixing*: 1 c.c., 2 c.c., 3 c.c., 4 c.c., 5 c.c., 6 c.c. In about eight minutes tests are begun by removing volumes of 5 drops from each digesting mixture by a pipette and adding this to 5 c.c. of the dilute iodin solution in a clear white test-tube standing over white paper. It is best to have a row of these tubes mounted to receive the liquids to be tested. If at the end of ten minutes drops from one of the flasks fail to give the iodin reaction we are ready for a second and more accurate test. Weigh out now 100 grams of the paste into each of six flasks, and, assuming that the endpoint in the first test was found between 4 and 5 c.c., add accurately to the six flasks these volumes of the diastase solution: 8 c.c., 8.4 c.c., 8.8 c.c., 9.2 c.c., 9.6 c.c. and 10 c.c. These volumes should all stand ready and all diluted to 10 c.c., so that they may be poured into the starch and shaken up without delay. They should also have the normal thermostat temperature of 40°, which precaution should be observed with the mixtures added in the first test. The tests with the iodin solution are repeated as in the first trial, and new limits are found between which the exact value must lie. For example, at the expiration of ten minutes the paste to which 8.8 c.c. of the diastase solution is added may show a faint yellowish dextrin color, while that with 9.2 is colorless. We may go further and try a series of new dilutions, but practically it is not necessary. In fact, we can not carry our readings to a much finer degree of accuracy, because of the difficulty of distinguishing between the effects of dilutions so near together, in many cases. In a case like the above illustration it is sufficient to take the mean of the last named dilutions, and calculate the results to the basis of one part of ferment and the starch converted by it.

6. We have recommended potato starch because it is possible to obtain it in a satisfactory condition of purity. The commercial corn starch, even after washing, does not appear to be suitable for the purpose. On microscopic examination the potato starch granules must appear clean and sharp.

The working method is seen to be simple, and if all the commercial diastase ferments are tested in this way their practical value may be easily compared. Until something better is proposed we believe the scheme as outlined may be safely followed, and that it will be perfectly fair to all concerned.

The above report was adopted by the Council, with the recommendation that before publication it should be submitted to the manufacturers whose products had been examined. The replies were reported to the Council by the subcommittee, and the following supplemental report was submitted to the Council and adopted:

This report has been submitted to the manufacturers of all of the articles described and opportunity given them to make any comment or criticism they saw fit to make. As might be expected, each firm was desirous of changing in some respect the wording of the report so far as it refers to the firm's products, but a careful consideration of these replies does not warrant the subcommittee in admitting the justness of any of the claims made.

Parke, Davis & Co. state that in testing their product, Taka Diastase, the reaction should be carried to the loss of blue color only, and claim that to digest to the loss of all color would work to their ferment "a very grave injustice." They say that "Taka-Diastase is recommended, not for the rapidity with which it converts starch into maltose and dextrose, but rather for its usefulness in carrying cooked starch through the preliminary stages of digestion or hydrolysis with remarkable rapidity." The subcommittee fails to see the force of this argument, since what is desired in a diastase is conversion of starch into sugar. Besides this, Taka Diastase does not appear to be any more rapid in the preliminary stages than are some of the others, and in the advertising literature it is praised for its power of sugar formation, as are all the others.

In the comments offered by Frederick Stearns & Co. objection is made to the passage in the report in which we point out the discrepancy between the digestion of 200 parts by weight of starch in ten minutes and the conversion of 200 parts of starch into sugars. The firm promises to correct this discrepancy, which should have been done long ago.

Fairchild Bros. & Foster object most strenuously to the position given Holadin in the table, and insist that by *their* method of testing, the product has a higher value than we give it. This, no doubt, is true, but the subcommittee is not concerned with the firm's method of testing, and must be allowed to employ its own, for the reasons pointed out in the report. The object is in part comparison, and for this uniformity of methods is necessary. In this connection it should be noted that in the past the firm has strongly favored the adoption of a uniform method of testing diastase products.

The manufacturers of Maltzyme write in a somewhat indefinite way of their disappointment in the findings of the report, but the letter calls for no special comment.

W. A. PUCKNER, Secretary.

INGLUVIN.

Report of the Council on Pharmacy and Chemistry.

A subcommittee of the Council reported that unwarranted claims and misrepresentation were made for Ingluvin by its manufacturers, William R. Warner & Co. recommended that the preparation be refused recognition and that the report be submitted to Warner & Co. for action.

The report was submitted to the firm, and after waiting one month and no acknowledgment or reply having been received, the Council directed its publication. It is as follows:

REPORT ON INGLUVIN.

Ingluvin is manufactured by W. R. Warner & Co., chemists, Philadelphia, Pa. The printed matter contains numerous claims and representations of which the following are specimens:

> "A positive specific for indigestion, dyspepsia and the most effective remedy in obstinate cases of vomiting of gestation. . . . A specific for vomiting in pregnancy in doses of from 10 to 20 grains, and a potent and reliable remedy for the cure of marasmus, cholera infantum, indigestion, dyspepsia, and sick stomach caused from debility of that organ. It is superior to the pepsin preparations since it acts with more certainty, and effects cures where they fail. . . . The natural glycocholic acid in Ingluvin is the active principle and the most efficient agent in the treatment of all stomachic and enteric disorders."

Two samples were purchased at different times in the open market and on examination found to consist essentially of powdered meat fiber mixed with what appeared to be a membranous tissue resembling the lining of a gizzard. Both samples on being tested by the method prescribed by the U. S. Pharmacopeia for estimating the strength of pepsin were found to possess little, if any, proteolytic activity. In order to determine whether or not the lining of a fowl's gizzard possesses proteolytic action, a fresh gizzard was secured, the lining washed slightly with water, then removed and on using one half of same in place of pepsin as prescribed by the Pharmacopeial method, it was found to digest 10 grams of albumin within the time limit. Pepsin, when properly kept, does not lose its strength to any material extent.

A careful examination was made for the presence of glycocholic acid, claimed to be the active principle of ingluvin, but its presence could not be established. Furthermore, the anatomic relations of the fowl are such as to preclude its presence.

The above shows that ingluvin does not possess nearly as much proteolytic activity as ordinary saccharated pepsin recognized by the 1880 Pharmacopeia and which was prepared on the basis of digesting 300 times its weight of egg albumin. Inasmuch as no glycocholic acid is present in ingluvin it would seem that saccharated pepsin would be far more efficacious in treating the abnormal conditions for which ingluvin is recommended in the advertising circulars. Furthermore, the claims made for the preparation are grossly extravagant.

A communication from Warner & Co. has been received since the above report was adopted in which it is stated: "The reason that previous letter was not replied to was because we were desirous of securing all the information possible on the subject. Since that time we have made considerable research and also made laboratory investigation, and are enclosing the accumulated data with diagram of a part of the alimentary canal showing the esophagus, crop and gizzard."

Much of the other matter submitted is immaterial. The following, so far as it means anything seems to confirm the correctness of the report of the Council's referee that ingluvin is practically devoid of proteolytic activity: " . . . the therapeutic activity must be due to the bitter property, rather than any proteolytic activity, and it probably increases, thereby, the functional activity of the stomach, by which the normal digestive process is increased. Ingluvin in a 0.4 per cent. hydrochloric acid solution at 37 to 40 C. or if mixed with an aqueous solution of pepsin under the same conditions possesses an acrid bitter taste and increases the secretion of the saliva and as this is practically the same condition as when in the stomach, it no doubt stimulates the depressed mucosa peptic glands and increases gastric secretion."

W. A. Puckner, Secretary.

COMMENT.

The fallacies attending the use of digestive ferments in most stomach diseases have been previously noted in The Journal.[1] In most digestive disorders a deficiency of the digestive ferment has not been proved. In cases in which pepsin is lacking, its administration is valueless unless it is combined with large doses of hydrochloric acid, and it is doubtful whether this combination is either necessary or conspicuously useful. There is, however, something so alluring about medication by digestive ferments which are assumed to supply a physiologic need, that since their discovery they have formed a fertile field for the activity of the manufacturer of proprietaries. As by scientific laboratory tests, it is possible to determine whether a given preparation has digestive power, the manufacturers of ingluvin avoid this point by claiming that the remedy acts, not on the food, but on the stomach itself. That remedies may exist which act as stimulants to the digestive secretions can not be denied, although at the present time this power has not been satisfactorily demonstrated. The proprietors of ingluvin finding that proteolytic activity is not to be attributed to this preparation of chickens' gizzards, announce a new therapeutic fact in the claim that "the natural glycocholic acid in ingluvin is the active principle and the most efficient agent in the treatment of all stomachic and enteric disorders." According to the report made to the Council there is no glycocholic acid in this preparation, nor is it possible, from the anatomic arrangements of the fowl's digestive apparatus, for it to get there. By all the tests which can be applied to determine its value this preparation is of much less value in digestive disorders than saccharated pepsin which was discontinued in the pharmacopeia because of its inferiority to the other forms of the ferment.

The repudiation, by the manufacturers, of the more absurd claims made for ingluvin, shows the need of maintaining an attitude of healthy skepticism toward the advertised therapeutic virtues of proprietary preparations. If a physician is disposed to use digestive ferments, he should give preference to the official preparations and ferments from other sources should be required to stand the exact tests which demonstrate the worthlessness of so many preparations on the market.

Religious Journals and Nostrums.

The editor of the *Gesundheitslehrer*, in commenting on the fact that a certain religious journal devotes one-third of its advertising to advertisements of unsavory "patent medicines," remarks: "What would the religious journals say if the medical journals were to devote one-third of their advertising space to announcements of things known to be directly contrary to all the teachings of the church?"

"Neriot Ferment."

Two handsomely dressed persons applied to a number of drug stores in Paris with a prescription calling for "Neriot ferment according to the formula of Dr. Henry (depot 129 Rue Montmartre)." The druggists sent to the depot and each bought a bottle of the ferment. It turned out that this depot had been rented for the day and a supply of bottles installed. The two swindlers decamped with the proceeds that evening, forgetting to pay the rent, but their landlord, finding the demand so lively, prepared more bottles and continued to sell the "ferment" until the police appeared. His "ferment" had the advantage of being harmless, as he used water alone.

Correspondence

Bacterial Therapy and Diagnosis of Gonococcus Arthritis.

Chicago, July 4, 1908.

To the Editor:—Referring to the editorial on Bacterial Therapy and Diagnosis of Gonococcus Arthritis, in The Journal, July 4, it would appear that the clinical reaction occasionally found following the administration of large doses of gonococcus vaccine was regarded as something recently discovered. It might prove a matter of interest, considering the importance attached to this statement, to know that such reactions are observed, at times, following the use of any vaccine. The local reaction at the site of inoculation is more common, consisting of a small nodule or indurated area beneath the skin, which is more or less sensitive to touch. The patient will frequently complain of this spot being sore or painful for several days after injection is made. If after several injections of vaccine a greatly increased dose is administered one may find a recurrence of the local reaction at all previous points of inoculation, as indicated by these tender indurated areas. Also, after an unusually large dose of vaccine, as I have observed in isolated instances, in the case of gonococcus and staphylococcus vaccines, at the time of injection the overlying skin may become red and hemorrhagic streaks may appear. A pronounced general reaction follows with exaggeration temporarily of the symptoms and signs of the local infection. The reaction at the site of inoculation in such cases may pursue a course similar to vaccination.

---

[1] Feb 2, 1907, 415 and Feb 9, 1907, 521.

Such consequences depend on the altered reaction of the organism toward the particular bacterial product. The extent of the reaction will depend on this factor, the quantity of vaccine employed and the method of administration. This holds true not only for tuberculin, but for all vaccines. I have observed pronounced clinical and stick (inoculation site) reactions, following the use of staphylococcus, streptococcus, gonococcus, etc., vaccines. The stick reaction (the tender nodule under the skin at the point of injection) is the more common and has diagnostic value. The injection of a very large dose for the patient of any vaccine, corresponding to the organism or organisms causing the disease, may give rise to a general reaction, rise of temperature, etc., as well as to a stick reaction, and is of diagnostic value, though neither is of decisive differential diagnostic value.

WILLIAM J. BUTLER, M.D.

New York Bovine Tuberculosis Inspection.

ALBANY, N. Y., *June 27, 1908.*

To the Editor:—I have read with interest the statements in THE JOURNAL of June 20, concerning bovine tuberculosis in New York State. Feeling sure that you wish to present the facts correctly, I submit the following:

The Allds-Lansing bill when introduced provided for an additional appropriation of $200,000. This was cut in the senate to $75,000, which amount finally passed. This, together with the appropriation made in regular session of our legislature, puts about $130,000 at the disposal of the commissioner of agriculture in connection with his work against contagious and infectious diseases of animals.

Our veterinarians visit herds where contagious or infectious diseases are supposed to exist. They always make a physical examination first. If tuberculosis is believed to exist, the owners of the herd are asked if they want the tuberculin test used and almost always they request it. We now have on file about sixty such requests. We attach great value to the tuberculin test, as it is the best means known for diagnosing tuberculosis. The physical test has some value and we are using it for what it is worth. It will reveal certain advanced cases of tuberculosis and certain bad cases of tuberculosis of the udder. Our experience has shown repeatedly that some cases of generalized tuberculosis, such as would undoubtedly result in the contamination of the meat of the animal, can not be recognized by physical examination alone, but, so far as we know, they are always found when the tuberculin test is applied.

The special point which I wish to make in connection with your statement is that we have not found the tuberculin test "unreliable as well as costly and cruel." You may be interested also to know that we are now killing such reacting animals as the owners do not wish to keep in quarantine. The killing is done under federal supervision, which permits the use of such meat as is found wholesome. This, we believe, removes the greatest objection to the use of tuberculin. It should not be overlooked also that our new amendment provides for larger payments to farmers for animals condemned on account of tuberculosis.

R. A. PEARSON,
Commissioner, Department of Agriculture.

Dr. Hoffa Not Born in America.

MILWAUKEE, WIS., July 5, 1908.

To the Editor:—Your Berlin correspondent, whom you introduced to your readers as a man of high standing, writes of the late Professor Hoffa: "He was closely related to Americans, as he was born in South America." Now, all the numerous biographies of Hoffa I have read state that he was born in South Africa and was never in America until a few years ago. My criticism may seem trivial, but such statements, if allowed to stand, may reflect on the authenticity of other interesting things your correspondent is telling us.

CHESTER M. ECHOLS, M.D.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

County Society Uses Local Newspapers.

The Jefferson County (Texas) Medical Society has begun the publication in the newspapers of popular articles on medicine. The *Beaumont Enterprise* for Sunday, June 28, contains an excellent article, signed by the Jefferson County Medical Society, on "The Progress of Medical Science," wherein the development of medicine from earlier times to the present is briefly but interestingly summarized. Such articles published impersonally by a society for the benefit of the people of the county can not fail to be of great educational advantage.

The Lay Press on Antivivisection.

One of the most striking results of the recent session of the American Medical Association is the widespread and general comment of the better class of newspapers regarding the work and aims of the Association. It is equally significant that the feature of the session which attracted the most attention was the recommendation for a Council for the Defense of Medical Research, in order to counteract the antivivisection agitation which has become noticeable in several states. It is particularly gratifying to note that the newspapers, without exception, condemned the attempts to restrict scientific investigation by the limitation of animal experiments as unwise and unnecessary, and recognized that the regulation of such matters could safely be entrusted to the medical profession. One of the most interesting of these comments appeared in the *Sioux City* (Iowa) *Journal*, in which the entire question is summarized with remarkable accuracy and clearness:

> The aggressive stand in favor of vivisection taken by the American Medical Association at its Chicago meeting has renewed interest in an old debate. . . . The decision of the Association was that inasmuch as there is an organized campaign to promote sentiment against the practice a counter campaign of education be undertaken in its behalf. It would seem that not much earnest effort along this line would be needed to cut the ground from under the antivivisection propaganda. The sentiment against vivisection has been cultivated mainly by societies for the prevention of cruelty to animals. These societies do noble and useful work in protecting our animal friends from unnecessarily cruel treatment by brutal or thoughtless human beings. In the matter of vivisection, however, the advocates of humanity have taken the wrong tack and allowed their espousal of animal rights to supersede their recognition of human rights. Our whole civilization has moved on the theory that animal life must be sacrified to preserve human life. This principle is involved in the defense of vivisection, but the prosecution refuses to look at the real merits of the case. . . . In the battle against the bacilli the only way in which victory can be won is by experiment. Shall the experiment be made with dogs and guinea-pigs, or with little children and their parents? Or shall there be no experiments, even though there be certain knowledge that a successful experiment would save annually the lives of tens of thousands of human beings during all the generations to come? The antivivisectionists seem to think that doctors do their experimenting for their own amusement, and that they take a sort of fiendish satisfaction in the suffering that attends their work. As a matter of fact, the doctors are working for humanity in a much more practical way than the sentimentalists who are criticizing the inhumanity of vivisection. There may be cruelty in the connection with animal sacrifice, but it is safe to say there is very little avoidable cruelty. The newspapers that are proposing legislation against vivisection are proposing a very poor bargain. They propose in effect to trade a great deal of human life and happiness for a very little animal life and happiness. It is a proposal that can not withstand a campaign of education.

The *Buffalo News* says editorially, speaking of the action of the Association:

> The reason is that so much unwisdom is uttered, such un-

sound arguments advanced against the practice of vivisection that the progress of medical science itself is seriously threatened with hindrance and delay from that cause. This danger is recognized frankly by the Association, and it feels that nothing is left it but war or submission to the judgment of ill-informed and hopelessly prejudiced sentimentalists. . . . The progress of medicine and surgery . . . in the last fifty years has been due largely if not mainly to the practice of vivisection in the hands of those competent to employ that resource of study. The campaign against vivisection lacks discrimination. Its purpose is to put a ban on the practice even in the hands of the most considerate and expert of operators. It must fail because on the question of relieving human pain at the risk of comparatively little pain to animals or of no relief to humanity the animals will have to suffer the pain for the sake of the human advantage.

One of the most interesting comments appears in the *Saturday Evening Post*, in which, after stating that there are at any given time several hundreds of thousands of people in the country who are "sore at the doctor" for various reasons and ready to take up any war-cry against him, the editorial continues:

> But before the Association's disturbance subsides, the antivivisection crusade will have been dropped in favor of some fresher crusade. We recall the able editor who conducted a brilliantly successful crusade to make the zoo people feed the big snake on bologna sausage instead of rats, and followed it by one, equally successful, for the extermination of rats. To people having human ties animal experimentation is preferable to human experimentation, and the choice lies between the two.

The *Saturday Evening Post* is quite right in stating that this crusade on the part of many of its followers will soon give way to an equally energetic and intelligent movement in support of some other fad, and that many of its followers enter into such agitation without the slightest investigation or knowledge of conditions and consequently soon drop it for some newer sensation.

But legislatures are often influenced by such appeals and bills are frequently passed and become laws with just as little knowledge of conditions, or investigation on the part of the legislators, as is possessed by the advocates of the measure. It consequently requires just as much effort to counteract a sentimental and ill-founded movement as it does to carry on a more serious and important campaign. The time and energy spent by the medical profession in the last ten years in successfully opposing legislation which would deprive physicians of opportunities for research work could far better have been spent in investigating diseases and developing improved methods of treatment and prevention for them.

If the medical profession can be entrusted with the care of the lives and health of the men, women and children of the country it can certainly be trusted with the far lesser duty of protecting dumb animals against needless and unnecessary pain and suffering. The term "vivisection," so frequently used by the advocates of legal restriction, is in itself misleading and inaccurate. Probably 80 per cent. of the animal experiments performed to-day are done with a hypodermic syringe and should be called vivipuncture rather than vivisection, since there is no cutting connected with any stage of the experiment. The suffering experienced by a thousand guineapigs is probably not equal to that endured by a single little child suffering from diphtheria or scarlet fever.

Association of State Secretaries and Editors of State Journals.

On Monday night, June 1, preceding the recent Chicago session of the Association, an important movement was inaugurated in the organization of the state secretaries and editors association. The meeting was called by a committee on organization appointed at Atlantic City of which Dr. Walter Cheyne of South Carolina was chairman. Over forty editors of state journals and secretaries of state associations met at the Victoria Hotel and sat down to dinner together, following which the meeting was called to order by Dr. Cheyne, who called Dr. George H. Simmons to the chair. Dr. E. J. Goodwin, editor of the *Journal of the Missouri State Medical Association*, was elected secretary. Dr. Cheyne detailed the correspondence he had carried on with various state secretaries and editors and said that a field of usefulness was open to the new organization and that he believed much benefit would follow its establishment.

DR. WISNER R. TOWNSEND, New York, secretary of the Medical Society of the State of New York, was called on to discuss "The Duties of the Secretary." He said in part that the question seemed to resolve itself into a matter of labor—how to do more work and do it well. There were efficient secretaries and inefficient secretaries, but rarely one who was absolutely inefficient. If the state secretary would watch the slothful ones, they could be displaced or encouraged to do good work. Among the important duties of the secretary was attendance at the annual session of the American Medical Association. It would be of great value to every county society if it sent its secretary. This would inspire the secretary with new determination to work for the growth of his society, for at these meetings were found so many men who were doing things that we could not fail to be enthused. This Association should advocate a uniform plan for all county societies for the collection of dues and reporting of membership lists to the American Medical Association. The state secretary should be a capable and willing officer. He should assist and guide the county secretaries in their work and encourage them to persist in keeping up interest in the county society, but should never "nag" nor publicly find fault, especially about trifling details. Each secretary may have a different method of getting the results, but if he succeeds that is all that should be asked. Dr. Townsend said it was a great pleasure to testify publicly to the good work done by the secretaries of the county societies in New York State.

DR. MELVILLE BLACK, Denver, secretary of the Colorado State Medical Society, spoke on medical organization of the present day. He said that medical organization from every standpoint was to be encouraged and fostered. This would fill an hiatus in the scheme of organization and would be productive of great good, not only to the secretaries and editors, but to the county and state societies and to the American Medical Association. Through the state journals the members could be brought into close touch with each other, and the knowledge that their papers would be published in the journal would stimulate greater interest in society work and encourage more frequent attendance at society meetings.

DR. PHILIP MILLS JONES, San Francisco, secretary of the Medical Society of the State of California, said that medical organization was as much a business as the printing of books or the running of railroad trains. We must reach out, not for the men at the top—they could take care of themselves—but for the men who were struggling along in the middle or at the bottom and even hypnotize them into the society. Medical men must be kept busy in medical work, for if they were not busy working together, they would be busy at each other. He said that he had represented medical journalism militant for the last six years. While he knew that this was not the ideal type of medical journalism, it was the only type that he conceived to be of value to the medical society. The medical association journals should be be absolutely clean and free from the taint of blood money. Six years ago we had no way of telling whether the manufacturer, who sent his representatives to our offices, was telling the truth about his preparations or was lying about them. As a matter of fact, we know that there is not a manufacturer who has not misrepresented some preparation. How shall we discriminate between the true and false? Shall we appoint a nice, respectable publication committee, who will take the copy of the advertiser and look over it and finding it apparently acceptable, approve it? This would simply mean nothing in regard to an accurate solution of the problem. The Council on Pharmacy and Chemistry was the proper body to consult in these matters, and we should back up the work of this council in every possible way. It was the only institution in the world where the physician can go and ask if the constituents of products put out by advertisers were truthfully reported and receive truthful answers.

DR. A. E. BULSON, Fort Wayne, Ind., editor of the *Journal of the Indiana State Medical Association*, spoke on "The Difference Between the Dependent Journal and the State

Society Journal." Dr. Bulson said that he was in hearty sympathy with the organization of this association. He described the growth of the Indiana State Medical Association from a membership of 800 to its present membership of 2,800. He commended the work of the Council on Pharmacy and Chemistry, and said that he thought its findings should be strictly followed by all state journals and that only articles approved by it should be advertised. He said that he had edited for a number of years a journal which was dependent absolutely on its advertising income, but that he had always endeavored to keep the reading pages free from advertising. He had continued to publish a dependent journal until conditions in the state made it possible to publish a state journal which should be clean and should represent the better class of men in the profession.

Dr. A. W. McAlester, Jr., Columbia, Mo., secretary of the Missouri State Medical Association, presented a draft of a constitution and by-laws for consideration. As adopted, provisions were made for an organization to be known as the Association of State Secretaries and Editors of State Association Journals, membership to be limited to the secretaries of the American Medical Association, the secretaries of state and affiliated branch associations of the American Medical Association and the editors of state journals. Annual meetings are to be held each year on the day preceding the annual session of the American Medical Association. The objects of the association are to cultivate a closer relation among the state associations, to establish improved and more uniform methods of conducting business, to promote the interests of the state journals and to develop the best method of conducting them and by cooperating with the officers of the American Medical Association to promote welfare of the profession.

The following officers were elected for the coming year: President, Dr. Walter Cheyne, South Carolina; vice-presidents, Drs. Philip Mills Jones, California, and W. R. Townsend, New York; secretary, Dr. L. H. South, Kentucky. Dr. Cheyne announced the following committees: Committee of secretaries, Dr. A. W. McAlester, Jr., chairman, Missouri; Dr. W. R. Townsend, New York; Dr. Thomas McDavitt, Minnesota; committee of editors, Dr. E. J. Goodwin, chairman, Missouri; Dr. I. C. Chase, Texas; Dr. A. W. McCormack, Kentucky.

Maryland Establishes a State Journal.

The first number of the *Bulletin of the Medical and Chirurgical Faculty of Maryland* was issued July 1, 1908. This is the first appearance of the eighteenth medical journal owned and published by a state association. Dr. H. O. Reik of Baltimore is the editor of the new journal, with Dr. J. A. Chatard as associate editor and Dr. John Ruhräh, secretary of the Medical and Chirurgical Faculty of Maryland, as an ex-officio member of the publication committee. In the foreword the editor states the position of the new journal plainly and positively. After emphasizing the importance of official journals as a means of communication between the different component parts of a medical organization, and the increased need of such a medium following reorganization, the alternatives and advantages of establishing such a journal are discussed. The purchase of an established journal is generally impossible on account of the expense. Considering the plan of publishing society proceedings in a journal over which the society has no control, the editor says:

> Such a policy can not fail to place the society in a most embarrassing position. It is folly to expect any journal owned and controlled by laymen to respect the higher ideals of the profession. All such papers are conducted for the purpose primarily of making money and the business manager is none too particular about discriminating between the revenue tendered by the advertiser of a fraudulent proprietary medicine and that offered with the advertisement of an honestly conducted hospital or pharmacy. Consider for a moment how ridiculous it appears to read in one portion of a journal the resolutions enthusiastically adopted by the state society endorsing the work of the Council on Pharmacy and Chemistry of the American Medical Association, and then, turning to the advertising pages, to find nearly all the articles condemned by the Council glaringly and brazenly setting forth their false or exaggerated claims to virtue. It is silly to try to delude ourselves with the notion that there is no relation between the advertising pages and those devoted to professional or scientific matters. . . . The journal that pretends to be honest and to condemn fraudulent preparations and yet makes its living from the publication of such advertisements is accepting blood money. The medical society that endorses such a journal or that continues to publish its proceedings in such a journal after having failed in an effort to correct the abuses, or, worse still, that profits by the admission of such advertisements to a journal of its own, is morally responsible for the fraud perpetrated.

The editor then reviews the recent action of the state house of delegates which instructed the council to inaugurate the publication of a monthly bulletin. To insure the cleanly character of the new publication, it was further provided by resolution that "no advertisement of any proprietary or patent medicine that has not received the endorsement of the Council on Pharmacy and Chemistry shall be accepted." The Medical and Chirurgical Faculty of Maryland is to be congratulated on the high stand taken by its house of delegates as well as the character of this, its first official publication. After Jan. 1, 1909, the *Bulletin* will publish all the important transactions of the state and county societies. It is welcome to the ranks of state journals and will without doubt prove of great value to the physicians of Maryland.

County Society Acts in Contract Practice.

The Jefferson County (Wis.) Medical Society has unanimously adopted resolutions providing that no member of the society shall enter into any contract or agreement with any society, lodge or association whereby an indefinite amount of services is required for a fixed fee. This is in accordance with the general principles on this subject previously suggested in this department. The evil in contract practice is not in the fact that a contract exists, but that, in practically all instances, the terms of the contracts as previously entered into have been unfair to all the parties concerned.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR. JOHN H. BLACKBURN, DIRECTOR.
Bowling Green, Kentucky.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month.

Fourth Weekly Meeting.

Carcinoma of the Liver.

Pathology.

Types of carcinoma, microscopic diagnosis of each. Gross appearances, (a) single tumor, with secondary deposits about it, (b) "Farre's tubercles" secondary to primary lesion. Primary or secondary cancer. Association of cancer and cirrhosis.

Symptoms and Diagnosis.

Symptoms: Variety and intensity of symptoms. Jaundice, pain, ascites, fever, cachexia, cerebral symptoms, metastases, the blood. Inspection, palpation, percussion.

Diagnosis: Carcinoma of pylorus or colon. Abscess, syphilis, benign tumors and hypertrophic cirrhosis of liver.

Cirrhosis of the Liver.

Atrophic.

Etiology: Alcoholism, age, sex, diet, acute infections, chronic diseases, cardiac and pulmonary lesions.

Symptoms: Prodromal symptoms. Obstruction to portal circulation. Gastrointestinal disturbances, spleen, urine, ascites. Toxemic symptoms. Facies, "caput Medusæ." Inspection, palpation, percussion.

Hypertrophic (Hanot).

Etiology: Sex, age, catarrhal jaundice, acute infections.

Symptoms: Onset, digestive disturbances. Jaundice, fever, pain, hemorrhages. Physical examination. Termination.

Biliary.

Etiology: Chronic obstruction to ducts.

Symptoms: Symptoms of cholangitis, jaundice, hepatic intermittent fever. Physical examination. Terminations.

Miscellany

Mendelism and Disease.—Mr. R. C. Punnett in an address before the Epidemiological Section of the Royal Society of Medicine (*Proc. Roy. Soc. Med.*, March, 1908), says that the recent work has served to confirm and extend the principles laid down by Mendel. He summarizes Mendel's law, using in illustration the possible variations between black, blue, and white, attainable by various crossings of these three colors in the Andalusian fowl, and sums up in general terms as follows: "The characters of plants and animals may in many cases be regarded as existing in alternative pairs. Corresponding to each member of such a pair is something representing it which may be carried by the gamete. These factors which the gamete carries are the channel by which the qualities of the parent are transmitted to the offspring. Every gamete contains one, and only one, of the factors corresponding to a given pair of characters, i. e., is pure for that character. For any given pair of characters, therefore, there can be two, and only two, classes of gametes: those pure for one member of the pair and those pure for the other member of the pair. But there can be three different kinds of zygote, for each zygote is formed by the union of two gametes; and since two kinds of gamete exist it is obvious that three kinds of union among them are possible. Two gametes, each pure for one member of the alternative pair of characters, may unite; or two gametes, each pure for the other member of the pair may unite; or, thirdly, two unlike gametes may unite. The zygote so formed contains representatives of each member of the pair, and is known as a *heterozygote* (hybrid), whereas zygotes containing representatives of but one member of the pair are termed *homozygotes*. Like the homozygote the heterozygote produces pure gametes; only it produces equal numbers of the two kinds instead of producing all of one kind. In this lies the explanation of the fact that hybrids mated together produce a definite proportion of the pure forms which subsequently breed true without ever giving a hint of their mixed ancestry." He discusses the results of breeding with the "dominant" and the "recessive" and catalogues a diversity of characters showing Mendelian inheritance, viz., size, structure, chemical properties, time of flowering, color, sterility and immunity (as to disease in wheat). He describes Biffen's experiment in crossing wheat, immune and susceptible to yellow rust, and considers it from the point of view of medicine probably one of the most important experiments ever made. Mendelian heredity in the human subject is illustrated by pairs of characters in eye color, brachydactyly, and certain forms of hereditary disease. Other points discussed are dihybridism, interdependence of characters and the nature of the alternative pairs, interaction of characters, gametic coupling, partial coupling, and sex limited diseases, explaining the limiting of hemophilia to males. Cases not dissimilar to those of sex limited diseases in man occur among animals, and he describes experiments by Mr. Baterson and himself in the transmission of pigmented characteristics in the silky fowl, where the unaffected male can transmit, but only to the opposite sex, which he hopes will throw light on diseases like hemophilia and peroneal atrophy. "There is little doubt but that a knowledge of Mendel's principles must be of value in the study of disease for when once Mendelian analysis has established the operation of the law and the nature of the characters concerned, we are in a position to predict always the probable, sometimes the inevitable, result of a given mating. When a brachydactylous man marries a normal woman we are certain that there is an even chance of any given child being born diseased or normal. When two normal people with night blind parents and grand parents marry we may predict with confidence that none of their children will inherit the disease."

In the hope of gaining information he suggests that diseases fall into at least three classes: "(1) Diseases which depend directly on a structural change in the gamete. by either the addition or subtraction of some character as compared with the normal, e. g., night blindness, brachydactyly, alkaptonuria. (2) Diseases in which such structural change of the gamete is without visible effect, but renders the individual liable to invasion by bacteria, etc. The disease is not manifested unless the structural change and the external organism are both present; e. g., rust in wheat. (3) Diseases caused by external invasion, for which immunity, as implied by gametic structure, is not known to exist, e. g., syphilis, ankylostomiasis. Of these three classes we should expect (1) and (2) to exhibit the phenomenon of Mendelian heredity in one form or another. But class (3) is of an entirely different nature and can not be inherited in the biologist's sense of the term. It seems not inconceivable that Mendelian analysis may be sometimes valuable as a criterion for separating this class of disease from the others."

Alleged Antitoxic Action of Salt.—A group of medical students at Buenos Ayres have been studying the action of salt as an antidote for curare according to the popular conception. Curare applied to a wound is not absorbed if salt is mixed with it or applied immediately afterward. Their experimental research is related in the *Revista del Centro Estudiantes de Med.*, viii, Nos. 77-79, 1908. It demonstrates that the addition of salt delays absorption of the curare, as also of any other poison, the salt inducing an osmotic current outward which interferes with the absorption of the poison. Any other chemical substance with this property answers the same purpose as the salt. It is exclusively a physical phenomenon.

Neutralizing Action of Cholesterin on Tetanus Toxin.—Almagia and Mendes have been conducting research at Rome in this line, and they found that cholesterin displayed a marked neutralizing power in respect to tetanus toxin, strychnin and curare. Otherwise fatal experimental doses of either were neutralized by injection of cholesterin, and also to a lesser degree by lecithin. Pulverized animal charcoal also neutralized otherwise fatal doses of strychnin in the animals. Tetanus toxin mixed in the test-tube with the charcoal did not seem to be influenced by it. Lecithin seemed to enhance the toxic action of curare while cholesterin apparently neutralized it. Their work is briefly mentioned in the *Münch. med., Wchnschr.*, April 14.

Book Notices

HANDBUCH DER BIOCHEMIE DER MENSCHEN UND DER TIERE. Herausgegeben von Dr. Phil. et Med. Carl Oppenheimer, Berlin. Erste Lieferung, mit 11 Abbildungen. Pp. 160. Paper. Price, $1.25. Jena: Verlag von Gustav Fischer, 1908.

Biologic chemistry is rapidly coming into its own as a distinct branch of the biologic sciences, instead of occupying its former suppressed position as either the handmaid of physiology or an ignoble offshoot of pure chemistry; in witness whereof we have the appearance within two or three years of new journals of biologic chemistry in America, England and Germany, as well as the newly formed and flourishing Society of Biological Chemists. One of the several reasons for the tardy advance of biologic chemistry was the ineffective and unsatisfactory methods of analysis that were available for the study of the highly complex substances with which this science has to deal; consequently its rapid development in the last few years has been associated with and largely the result of improvements in analytical methods. The "Handbuch der Biochemie," therefore, has the important function of collecting these analytical methods from their scattered sources in articles on original research, and making them available for the research worker and for the clinical laboratory. This valuable enterprise will undoubtedly meet a hearty reception from the large and increasing number of chemists, biologists, and physicians who are applying chemical methods to research, diagnosis and therapeutics; and its quality is assured by the reputation of its editor and the large staff of associates. The scope of the publication is shown by the fact that it will appear in twenty separate sections, each about 160 pages in length. Such a book is much needed, and it will undoubtedly be found soon on the shelves of every well-equipped laboratory of physiology, biology, chemistry or biologic chemistry.

Practical Treatise on Fractures and Dislocations by Lewis A. Stimson, B.A., M.D., etc., Professor of Surgery in Cornell University Medical College, New York. Fifth Edition, Revised and Enlarged. Illustrated. Cloth. Pp. 847. Price, $5.00. New York and Philadelphia: Lea Bros. & Co., 1907.

About one-third of this volume is devoted to a presentation of the etiology, pathology, diagnosis, prognosis and general principles of treatment, the remainder being given to special diagnosis and treatment of the various forms of this class of injuries.

Valuable additions have been made to this edition from the accumulation of the literature of late years based on the revelations of the Roentgen rays regarding injuries of the small bones of the wrist and foot and of the ends of the long bones. The large amount of material at the command of the author has been utilized to make this book one of the most complete from the clinical standpoint in the English language. There have also been added many new cuts and skiagrams, the latter helping to make clear the exact nature of some forms of fractures and dislocations which recently have been only partially or not at all recognized.

The entire work is authoritative and a safe guide for the practitioner as well as for the student.

We would specially commend the views of the author on the question of direct fixation of the bone fragments in fractures; he prefers temporary direct fixation or fixation by absorbable suture to direct fixation by non-absorbable suture or metallic apparatus. While admitting the value of the Roentgen rays in some obscure cases, in fractures of the small bones and in fractures near joints, Dr. Stimson points out that errors of interpretation are frequent. The skiagram should be interpreted by the aid of the clinical findings and of considerable experience in its use. He is conservative and we believe therefore correct in his views regarding treatment of fractures of the vertebra and of the patella.

The Newer Remedies. By Virgil Coblentz, A.M., Phar.M., Ph.D., F.C.S. Professor of Chemistry in Columbia University, Department of Pharmacy. Fourth Edition, Revised and Enlarged. Cloth. Pp. 133. Boston: The Apothecary Publishing Co., 1908.

In this book the composition of the newer remedies is given in accordance with the statements of the manufacturers, except, as the author states in the preface, in those instances in which analyses have been published by independent investigators. Coblentz calls attention to the work in this line being done by the Council on Pharmacy and Chemistry of the American Medical Association, the Pharmaceutical Laboratory of Berlin University, and by Drs. Zernik, Koch and Aufrecht, whose publications appear in the *Apotheker Zeitung*, the *Pharmaceutische Centrahalle* and the *Pharmaceutische Zeitung*. In most instances the remedies are listed and described under the proprietary name, a cross reference being made to the chemical name—for example: acetyl-salicylic acid—aspirin. Phenalgin is given as a synonym for ammonol. The analysis published by the Council on Pharmacy and Chemistry for this latter preparation is given, but there is no credit to either the Council or The Journal, in which it appeared June 3, 1905, the inference being, naturally, after reading the statement in the preface above referred to, that the analysis is that furnished by the manufacturers. The same criticism applies to the analysis of orangeine. No mention is made of the adverse reports of the Council on tartarlithine, uron and thialion. In some other cases, as for example Tyree's powder and oxychlorin, reference is made to the published reports of the Council.

Meat and Food Inspection. By Wm. Robertson, M.D., D.P.H., F.T.S., Lecturer on Public Health. Royal College for Surgeons, Edinburgh. Cloth. Pp. 372, with illustrations. Price, $3.50. Chicago; W. T. Keener & Co., 1908.

While the training of a veterinarian is needed to meet the more complicated problems arising in the inspection of animals intended for food, Dr. Robertson holds that every student of medicine possesses the requisite knowledge of pathology to pronounce opinions on pathologic conditions of animals intended for food and that even the intelligent layman after close study can become a judge of the wholesomeness of meats. Considering the importance of the subject it is strange that so little attention has been paid to it. Where the sanitary authorities can not afford to employ a special veterinarian, the health officer should fit himself for the ordinary duties of food inspection. To assist the latter in such preparation, the author has included in the scope of his work the inspection of stables, pigstyes, milk-shops, etc., as well as the inspection of slaughter-houses and meat. These subjects occupy the first half of the book, while the second half consists of the laws relating to food inspection, those in force in the United States being given by Dr. Maximilian Herzog in an appendix. The volume, although of special value to British officers, ought also to be very serviceable to American sanitary authorities. It is well illustrated.

The Efficient Life. By Luther H. Gulick, M.D., Director of Physical Training in the New York City Schools. With Double-page Frontispiece. Cloth. Pp. 195. Price, $1.20 net. New York: Doubleday Page & Co., 1907.

Gulick appropriately dedicates his book "to Theodore Roosevelt, who sometimes leads the simple life, who often leads the strenuous life, but who always leads the efficient life." The volume may be put into the hands of patients who wish advice about eating, sleeping, bathing, exercising and, in general, putting the body into a condition in which the greatest efficiency may be obtained. The soundness of the advice may be illustrated by the following on stimulants: "It is never safe to consent to dose a man up, unless you can get him to give you his word of honor that he will give himself a corresponding vacation as soon as the special strain is over." And this: "Pain is like a danger signal on a railroad. . . . There are times when it is perfectly right to aim at the pain. . . . Perhaps some important work must be carried through." When a man stops the pain with drugs, "from that moment on he has assumed absolute responsibility for the conditions, whatever they are, that gave rise to the pain. . . . A headache powder does not hit the cause of the headache any more than a laxative hits the cause of constipation or a spoonful of pepsin the cause of indigestion."

Les Pseudo-Bacilles Acido-Résistants. Critique des méthodes de coloration du bacille tuberculeux. Révision du groupe des bacilles dits acido-résistants. Par le Dr. André Philibert. Travail du Laboratoire de bactériologie de la Faculté de médecine de Paris. Paper. Pp. 144. Paris: G. Steinheil, Editeur, 1908.

This is a monograph from the laboratory of bacteriology of the University of Paris, containing a thorough consideration of the causes and significance of the acid-resisting property of *Bacillus tuberculosis* and a few other organisms. Some of the conclusions reached are of great importance for practical diagnosis, and they are probably warranted. Among them are these: True acid-resisting bacteria consist of two groups, the *B. tuberculosis* in all its varieties, and the "tuberculoid" bacteria of milk, grains, grass, etc. There also is a third group of acid-resisting bacteria which have been found in urine, smegma, sputum, sebaceous material, fibrinous exudates, and in cadavers, in which this staining property is an acquired character, perhaps due to the character of the soil in which the organisms have been grown. It is of course important that these organisms be distinguished from the true tubercle bacilli, and this is not difficult because, though acid-resistant, they are not alcohol-resistant. Consequently, if in staining the decolorization is made with alcohol according to the regular Ziehl-Neelsen method, the forms of this third group will be decolorized.

Formulaire Synthétique de Médecine. By Dr. L. Prod. Pp. 601. Price, 6 fr. Paris: Jules Rousset, 1908.

This formulary book, suited especially to the needs of French physicians, is constructed on a somewhat different plan from other similar works. It aims to give the properties of medicines and at the same time their therapeutic indications and to analyze from the therapeutic side the indications for treatment afforded by individual symptoms. Not only are the indications for each remedy given, but the contraindications are also pointed out. Other methods of treatment besides drugs, such as climate, mineral waters, electricity, etc., are included. The book is of a convenient size for the pocket and bound with flexible covers.

Taschenbuch der Physiologie By Prof Dr Med H Boruttau, Berlin Vols I and II Paper. Price, $6 00 per set. Leipzig Dr Werner Klinkhardt, 1908

This represents a German variety of that familiar pedagogic abomination, the "quiz compend," which seems generally to be constructed with the sole object of making thinking an unnecessary accomplishment, and of substituting the habit of mental cold storage of facts and near-facts in place of habits of observation and deduction. The quality of a medical school may be estimated as in inverse proportion to the use its students find for this sort of publication.

Commoner Diseases of the Eye By Casey A Wood, M D, C M, D C L, Professor of Ophthalmology, Northwestern University Chicago, and Thomas A Woodruff, M D, C M, L R C P. (London), Ophthalmic Surgeon, St Luke's Hospital and St Anthony de Padua Hospital, Chicago Third Edition, Enlarged and Improved Cloth Pp 598 Price, $2 50. Chicago W T Keener Co, 1907

In the new edition this excellent little volume has been enlarged and much improved, making it more than ever a practical text book for the general practitioner who must be acquainted with all the common eye affections and yet cannot give time to master all the details of volumes for specialists.

The Sanitation of Recreation Camps and Parks By Dr Harvey B Bashore, Medical Inspector for Pennsylvania Department of Health First Edition Pp 109, with illustrations Cloth Price, $1 00 New York John Wiley & Sons London Chapman & Hall, 1908

This little work details the sanitation of camps, whether military, labor, hunting or recreation, and the keynote of it all is pure water and the proper disposal of waste

Queries and Minor Notes

Anonymous Communications will not be noticed Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed

COMPOSITION OF GOAT S MILK

Feslin, Egypt, June 14, 1908

To the Editor —Kindly give me the percentage of fat proteid, etc, in goat s milk as compared with cow s milk

H E Hanson

Answer —According to Bunge (Text Book of Physiologic and Pathologic Chemistry, second English edition), one hundred parts of milk contain

	Cow	Goat
Casein .	3 0	3 2
Albumin .	0 5	1 1
Total proteids .	3 5	4 3
Fat ..	3 7	4 8
Sugar of milk	4 9	4 5
Ash . ..	0 7	0 8

REPTILES DO NOT LIVE IN HUMAN STOMACH

Great Mills, Md, June 23, 1908

To the Editor —Is it possible for a snake or reptile to live in the human stomach?

H A Brooks, M D

Answer —No authentic case is known of the existence of a living, air breathing animal in the human stomach The accounts of such conditions are founded on abnormal sensations erroneously interpreted by credulous people to indicate the presence of a living animal The cases should be treated in such a way as to remove, if possible, the morbid sensations and at the same time dispel the delusion founded on them

COMPRESSION THERAPY IN GYNECOLOGY.

Louisville, Ky

To the Editor —Please refer me to some book or article that gives indications and technic in the use of the colpeurynter filled with mercury This method, called the weighting treatment, is referred to in The Journal, Jan 25, 1908, in an abstract on page 323

R R Elmore

Answer —This method of gynecologic treatment was evolved by Ludwig Pincus of Danzig, Germany, and described by him in a monograph entitled "*Belastungslagerung, Grundzuge einer nicht Operative Behandlung chronischentzundlicher Frauenkrankheiten und deren Folgezustände,*" Wiesbaden, 1905 J F Bergmann A description of the method is also given in the *Monatsschrift für Geburtshulfe und Gynakologie*, xxi, 71 A short abstract was also published in The Journal, May 20, 1905, xliv, 1650

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S Army, week ending July 4, 1908

Kirkpatrick, T J, major M C, ordered from Ft Moultrie, S C, to Chickamauga Park, Ga, for duty

Baker, F C, capt, M C, ordered from Ft Oglethorpe, Ga, to Chickamauga Park, Ga, for duty

Wickline, W. A, capt, M C, left Army G H, San Francisco, with one half of Co B H C, for duty at Leon Springs, Texas

Zinke, S G, capt, M C, ordered with Field Artillery from Ft Leavenworth, Kans, to Ft D A Russell, Wyo, for duty during the maneuvers

Vose, W E, capt, M. C, ordered from Ft Des Moines, Iowa, to Ft Mackenzie, Wyo, for duty in the field

Reynolds, C R, capt, Cowles, C D, Jr, first lieut, Huber, E G, first lieut, and Lambie, J S, Jr, first lieut, M C., left Gen Hosp, Washington, D C, with 50 men of Co C, H C, for Chickamauga Park, Ga, Field Hospital No 8

Whaley, A M, capt, M C, left Ft. Sam Houston, Texas, for duty at camp, Leon Springs, Texas

Lamson, T, capt, M. C, granted leave of absence for two months, with permission to ask extension of one month

Manly, C J, capt, M C., granted leave in the United States from July 12 to Sept 15, 1908

Clark, J A, capt, M C, relieved from further duty at Ft Oglethorpe Ga, and temporary duty at Madison Barracks, N Y, and ordered to proceed Aug 1 to Ft Liscum, Alaska, for duty

Hanson, L H, first lieut, M C, when relieved at Ft Liscum, Alaska, ordered to Seattle, Wash, for orders

Grissinger, J W, capt, M C, relieved from duty at Ft Ethan Allen, Vt, and ordered to proceed Aug 1 to Ft Egbert, Alaska, for duty

Schmitter, F, capt, M C, when relieved at Ft Egbert, Alaska, ordered to Seattle Wash, for orders

ALABAMA

Coleman, S L, Uniontown.
*Copeland, M A, Birmingham
Wilkinson J G, Catherine
†Wyman, B L, Birmingham

ARIZONA

Ayer, Ira, Cochise County.

ARKANSAS

*Dickson, H N, Paragould
Lloyd, C J, Harrison
*Grammer, J B, Searcy
Isom, Alphonso Gould
†Williams F M, Hot Springs
*Wood, T F, Uniontown

CALIFORNIA

Bine, Rene, San Francisco
*Briggs, C A, Pasadena
*Crabtree, H T, San Francisco
Eckardt, A O, Gualala
Fisher, C V, Antioch
†McCarty, I. A, Los Angeles
Nicholls, R J, San Francisco

COLORADO

*Herrick, J C, Denver
Melvin, W G, Ouray
†Pattee, J. J, Pueblo

CONNECTICUT

Clifton, H C, Hartford
Lowe, H R, Putnam
*Whittemore, E R, New Haven.

WASHINGTON, D C

Gannon J. A, Washington
Verbrycke, Jr, J R, Washington
Waring, J H, Washington

FLORIDA

†Pittman, J H, Jacksonville

GEORGIA

Burford, R E L, Brunswick
Cole, J E, Middleton
Harrington, A F, West Point.
†Matthews, M F, Athens
Respess, Herbert, Macon
Smith, S S, Athens

ILLINOIS

Adair, Sadie B, Chicago
†Albers, Anna, Chicago
Albright, I N, Chicago
†Alford, E T, Chicago
*Allen, T. G, Chicago
†Armstrong, Kate L, Kewanee
†Bacon, J V, Chicago
†Bailey, G L, Oak Park
†Bailey, H V, Pekin
†Baird, B D, Galesburg
Baker, G. J, Marion
†Balderston, S V, Evanston
†Baldridge, S T, Chicago
†Barnard, H. S, Chicago
*Baur, E F, Chicago
Bentele, Elizabeth, Chicago
†Bergeron, J Z, Chicago
*Biehn, J F, Chicago
*Blackburn, W. R Breeds
†Blakelidge, Rose M La Grange
Bonthius, F A, Chicago
†Booth, F H, Chicago
Bouton, W. C, Waukegan
†Bradley, E H, Peoria
†Brenner, F T, Quincy
†Breuer, E J, Shabbona
*Brian, J R, St Francisville
*Brodrick, F. W., Chicago
Brown, W C, Chicago
†Brucker, M W Chicago
Brownfield S T, Galesburg
†Burcky, W E, Chicago
†Burns, P T, Chicago
†Bush, Bertha E, Chicago
†Camp, F K Chicago
†Chancellor, P S, Chicago
†Chapin, C W, Weldon
*Chapin, H A White Hall
*Christie, Edmund, Chicago
†Christman, Paul, Kankakee
Church, Harry S, Modoc
†Clark, C P, Chicago
Clark, T H, Golconda
†Clark T. H, Chicago
*Cloyd, F N, Westville
*Cloyd, R A Catlin
Cody, J M, Tremont
*Collins, H O, Paloma
*Cook, C E, Mendota
*Corcoran, A L, Peoria
Coughlin, F J Aurora
†Coveny, M J, Spring Valley
Culbertson O J, E St Louis
†Cunningham, W J M, Chicago
†Curry, N D, Chicago
†Curtis W P, Chicago
Dale, G L A, Chicago
*Dale H W, McLeansboro
†Dahlberg, A V, Chicago
*Danford R C, Pana
*Deal, John, Riverton.
*DeVault, A N Chicago
*Dicus, J F, Streator
*Dods G D B, Chicago
†Donkle, L B, Chicago
*DuBois, W L, Chicago
Duntley, G S, Bushnell
†Dvorak, G M, Chicago
†Dyche, G B Chicago
*Eckard, E M, Peoria
†Einarson, B Chicago
†Ellingwood, C V, Chatsworth.
†Ellis, I B, Chicago.
Ennis, Matilda E, Chicago
*Epperson, J. C, Kansas
†Erickson, C A, Chicago
*Eskey, F. W, Tuscola
*Faith, Thomas, Chicago
†Folckemer, H R, Bowen
†Ford, E J, North Evanston
†Foreman, C B, Kane
†Fouser, Hiram, Harvey.
†First, F H, Rock Island
*Fisher, J. C, Decatur
*Fletcher W. R, Joliet
*Fricke, G. H, Park Ridge
*Gabel, H. G, Aurora
†Gillespie, E S, Wenona
*Gobble, H W., Greenfield
†Goldberg, J. B, Chicago
Gorrell, T J. H, Chicago

Medical Education and State Boards of Registration

COMING EXAMINATIONS.

NEW MEXICO Board of Health and Medical Examiners, The Capitol, Santa Fe, July 13-14. Secretary, Dr. J A Massie, Santa Fe

ARKANSAS Regular Board of Medical Examiners, State Capitol Bldg, Little Rock, July 14. Secretary, Dr. F. T. Murphy, Brinkley

ARKANSAS Homeopathic Board of Medical Examiners, Little Rock, July 14 Secretary, P. C. Williams, Texarkana

ARKANSAS Eclectic Board of Medical Examiners, Little Rock, July 14 Secretary, Dr A. J. Widener, Little Rock.

CONNECTICUT Homeopathic Medical Examining Board New Haven, July 14 Secretary, Dr. Edwin C. M. Hall, 82 Grand Ave, New Haven.

CONNECTICUT Eclectic Medical Examining Board, Hotel Garde, New Haven, July 14. Secretary, Dr. T S Hodge, 16 Main St, Torrington

CONNECTICUT Regular State Medical Examining Board, City Hall, New Haven, July 14-15 Secretary, Dr Charles A Tuttle, 196 York St, New Haven

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, July 14 Secretary, Dr. George C Ober, 210 B St, S E. Washington

WEST VIRGINIA State Board of Health, Charleston, July 14-16 Secretary, Dr. H A Barbee, Pt Pleasant

MASSACHUSETTS Board of Registration in Medicine, State House, Boston, July 14-16 Secretary, Dr. Edwin B Harvey, Room 159, State House, Boston

VERMONT State Board of Medical Registration, Burlington July 14-16 Secretary, Dr W. Scott Nay, Underhill

WISCONSIN Board of Medical Examiners, Park Hotel, Madison, July 14-16. Secretary, Dr J V. Stevens, Jefferson

NEW HAMPSHIRE State Board of Medical Examiners, State Library, Concord, July 15-16 Regent, Mr H. C. Morrison, Concord

Cincinnati Colleges Merge.

We are informed that the long contemplated merger between the Miami Medical College and the Medical College of Ohio, both of Cincinnati, has finally been consummated; the new college thus formed will be the Medical Department of the University of Cincinnati. Already extensive plans have been made to develop the school A professor of pathology is to be secured at a salary of $4,000 a year, who will also be in charge of the extensive laboratories at the Cincinnati Hospital The school will have full use of the clinical material of the Cincinnati Hospital, which at present has nearly 600 beds Within the next few years a new hospital is to be erected at a cost of about $3,000,000 This merger ends the rivalry which has existed between the two faculties for many years It is noteworthy that they have been willing to lay aside their differences, and even to make personal sacrifices in order that Cincinnati might have one strong medical college of high standard The new school should receive the support of the alumni of the two schools, as well as of the medical profession generally.

Errata in State Board Statistics.

Some errors in percentages occurred in the State Board Statistics published in THE JOURNAL, May 30, 1908. The percentage for Howard University in the 18th line, on page 1857, should be 23.5 instead of 41.2 The same correction should be made in Table K, on page 1846 On page 1844, in Table G, the percentage of failure for the University of Pennsylvania, "in other states," should be 1.6 instead of 6.2

Rhode Island Requires Graduation.

An amendment to the Rhode Island medical practice act provides that every applicant for license hereafter must hold a diploma from a reputable medical college and gives the board the right to refuse recognition to medical colleges which are not doing satisfactory work.

California April Report.

Dr. Charles L. Tisdale, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at San Francisco, April 7-9, 1908. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 58, of whom 34 passed and 24 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Cooper Med. Coll.	(1907)	79
University of California	(1907)	79.2, 81.4
University of Southern California..(1906) 82.5;	(1907)	76, 80
College of P. and S., San Francisco..(1902) 75.2;	(1907)	78.6

Idaho April Report.

Dr. W. F. Howard, secretary of the Idaho State Board of Medical Examiners, reports the written examination held at Cœur d'Alene, April 7-8, 1908. The number of subjects examined in was 13; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 27, of whom 21 passed and 6 failed. The following colleges were represented:

PASSED.

College.	*Year Grad.*	*Per Cent.*
Denver and Gross College of Medicine	(1907)	78.9
Denver College of Medicine	(1888)	88
College of P. & S., Chicago..(1903) 79.8; (1906) 75.9	(1907)	79.5
Rush Medical College..(1893) 82.6; (1897) 75.8;	(1902)	89.3
National Medical University	(1905)	82.4
Kansas Medical College	(1895)	81.4
Kentucky School of Medicine......(1901) 83.7;	(1905)	80.4
Harvard Medical School	(1899)	83.7
University of Michigan	(1886)	92
Missouri Medical College	(1895)	75
Creighton Med. Coll.........(1905) 79.6, 84.8;	(1907)	78.5, 86.7
Woman's Med. Coll. of Pennsylvania	(1895)	83.1
University of Virginia	(1904)	75

FAILED.

Bennett Coll. of Ecl Med and Surg..	(1894)	53.1
Detroit College of Medicine	(1906)	69.4
College of P. and S., St. Louis	(1903)	68.1
Missouri Medical College..	(1894)	69.2
Barnes Medical College....	(1898)	2 3
Vanderbilt University	(1900)	62.7

Massachusetts May Report.

Dr. E. B. Harvey, secretary of the Massachusetts Board of Registration in Medicine, reports the written examination held at the State House, Boston, May 12-14, 1908. The number of subjects examined in was 13; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 50, of whom 24 passed, including one non-graduate, and 22 failed, including 5 non graduates. The following colleges were represented:

PASSED.

College	Year Grad	Per Cent
Maryland Med. Coll	(1905)	79.4
University of Maryland	(1889)	75.2
Boston University	(1907)	75
Harvard Medical School	(1908)	77.7
Tufts College Medical School	(1900)	78.9
Dartmouth Medical College,	(1894) 79; (1907) 75; (1908)	75, 78.2, 78.5, 80.8
Albany Medical College	(1907)	75
New York Homeopathic Med Coll	(1902)	79.9
Bellevue Hosp. Med Coll	(1888)	82.7
Jefferson Med Coll	(1897) 76.5; (1907)	77.7
Woman's Med. Coll. of Pennsylvania	(1907)	81
University of Vermont	(1898)	79.5
Queen's University, Kingston, Ont.	(1902)	81
Laval University, Quebec	(1902)	75.
McGill University, Montreal	(1907)	75, 77
Dalhousie University, Halifax, Nova Scotia	(1903)	80.6
Nongraduate		79.4

FAILED.

College	Year Grad	Per Cent
Georgetown University	(1906)	72.5
Howard University, Washington	(1907)	71.6

College of P and S, Boston	(1905) 67; (1906) 61; (1907)	67.7
Laval University, Quebec	(1906)	67.4
Imperial Alexanders University, Finland, Russia	(1902)	69.7
Nongraduates		53.3, 64.6, 65.2, 68.6, 73.5

Illinois Medical Colleges in Good Standing.

The Illinois State Board of Health announces for the information of medical colleges, medical students and those who may be about to take up the study of medicine, that the following medical colleges in the state of Illinois are in "good standing" with the State Board of Health:

Bennett College of Eclectic Medicine and Surgery, Chicago
Chicago College of Medicine and Surgery (formerly the American College of Medicine and Surgery), Chicago
College of Physicians and Surgeons, Chicago.
Hahnemann Medical College, Chicago
Hering Medical College Chicago
Illinois Medical College, Chicago
Northwestern University Medical School, Chicago.
Rush Medical College, Chicago

At the meeting held June 23, the Illinois State Board of Health declined to reinstate the National Medical University in "good standing" and by unanimous vote reaffirmed the action of the board taken March 15 1907, when the National Medical University was declared not in "good standing"

Marriages

Virgil Abel, M.D., to Miss Mabel Boas, both of Vallonia, Ind., June 12.

Fonrose Lawson, M.D., Sullivan, Ill., to Miss Helen Greer of Gays, Ill., June 10.

C. C. Dougherty, M.D., to Miss Florence Meiklee, both of Philadelphia, June 17.

J. F. Cutler, M.D., to Miss Imogene Brigham, both of Philadelphia, June 19.

W. H. Liphert, M.D., to Miss Ida R. Lippincott, both of Philadelphia, June 17.

H. A. Ross Coppage, M.D., to Miss Mabel E. Fowler, both of Baltimore, June 18

Bert F. Gleason, M.D., to Miss Adeline S. Miller, both of Arthur, Iowa, June 20.

Charles E. Stauter, M.D., to Miss Sadie Wolfe, both of Baltimore, Md., June 6.

S. A. Shadrach, M.D., Baltimore, to Miss Sallie R. Brown, at Danville, Va., June 9.

George G. Taylor, M.D., Chicago, to Miss Ethel G. Hickok of Allegan, Mich., June 10.

Harlan Shoemaker, M.D., Philadelphia, to Miss Grace Clyde Gilman of New York City, June 4.

William Rudolph Boost, M.D., to Miss Mabel Wilson, both of Falls City, Neb., June 24.

David A. Baker, M.D., Bowman, N. D., to Miss Ollie Clark of Denver, Ill., recently.

John C. Jacobs, M.D., Spicer, Minn., to Miss Mattie Lien of Willmar, Minn., recently.

Henry McGuigan, M.D., Mazeppa, Minn., to Miss Catherine Zender of Austin, Minn., June 16.

Frank Barrows, M.D., Boise, Idaho, to Dessie B. Robertson, M.D., of Boulder, Colo., June 17.

John A. Freeman, M.D., to Miss Edna Marks, both of Beard, Ky., at O'Bannon, Ky., June 17.

William Preston Hoy, M.D., to Miss Eleanor Beverley Constable, both of Petersburg, Va., June 16.

William Fletcher Hall, M.D., Crisfield, Md., to Mrs. Clara J. Benson of Wilmington, Del., June 17.

Wiley Leon Whitehead, M.D., Lake City, S. C., to Miss Bessie Branch Keels of Lynchburg, S. C., recently.

Joseph Haskell Chiles, M.D., Oviedo, Fla., to Miss Ida Miller Howard of Pulaski, Va., in Jacksonville, Fla., June 17.

Deaths

Furman J. Shadd, M.D. Howard University Medical Department, Washington, D. C., 1881; a member of the Medico-Chirurgical Society of Washington, D. C.; for thirteen years assistant surgeon at the Freedman's Hospital, Washington; professor of materia medica and therapeutics, and secretary and treasurer of the Medical Department of Howard University; one of the most prominent colored practitioners of Washington; died at his home, June 24, as the result of a general nervous breakdown, after an illness of several months, aged 54.

Peter V. Burnett, M.D. New York University Medical College, 1876; of Brooklyn, N. Y.; a member of the Medical Society of the State of New York; physician to the Eastern Dispensary and Nose, Throat and Ear Hospital; who was under treatment in Mount Sinai Hospital, New York City, on account of overwork; leaped from the roof garden of the hospital, June 29, and was instantly killed.

John Gilman McAllister, M.D. College of Physicians and Surgeons in the City of New York, 1866; a member of the Massachusetts Medical Society; president of the Lawrence (Mass.) board of U. S. pension examiners; a veteran of the Civil War and a member of the consulting staff of the Lawrence General Hospital; died from heart disease, June 20, after an illness of six months.

James Park West, M.D. Medical College of Ohio, Medical Department of University of Cincinnati, 1882; a member of the American Medical Association and American Pediatric Society; United States pension examining surgeon at Bellaire, Ohio; a well-known specialist in diseases of children; died at his home in Bellaire, June 25, from facial erysipelas, after a short illness, aged 49.

George M. Walker, M.D. University of Tennessee, Medical Department, Nashville, 1888; a member of the American Medical Association; one of the oldest practitioners of Hamilton County, Tennessee, and for several years physician to the New Soddy Coal Company; died at his home in Soddy, Tenn., June 21, after an illness of two weeks, aged about 60.

John G. VanDeveer, M.D. Kentucky School of Medicine, Louisville, 1903; a member of the American Medical Association; formerly a practitioner of Fairland, Okla., and an interne in the City Hospital, Louisville; died in his room in Louisville, June 27, from multiple neuritis and heart disease, after an illness of five weeks, aged 32.

William M. Michel, M.D. Georgetown University School of Medicine, Washington, *D. C.*, 1870; for several years a physician at the Round Valley and Hoopa reservations: who was injured May 1 by a fall which caused paralysis; died at his home in Ferndale, Cal., as a result of his injuries, June 15. aged 68.

Daniel W. Lynch, M.D. Northwestern University Medical School, Chicago, 1875; a member of the American Medical Association; local surgeon at West Bend. Wis., for the Chicago & Northwestern Railway; died at his home in that city, June 25, after an illness of six weeks. aged 60.

Samuel B. Lightner, M.D. Jefferson Medical College. Philadelphia, 1863; a member of the American Medical Association; a member of the U. S. pension board of Clinton County, Ohio; and local surgeon of the Baltimore & Ohio Railroad at Sabina: died at his home, June 24. aged 68.

George W. Jones, M.D. Louisville (Ky.) Medical College. 1886; of Denham Springs, La.; a member of the Louisiana House of Representatives; was killed in the wrecking of a train at the crossing of the Baton Rouge and Hammond and Red River Valley Railroads, June 23.

Pelatiah Fitch, M.D. Jefferson Medical College, Philadelphia. 1862; assistant surgeon of the Eighth New Jersey Volunteer Infantry and surgeon of the Tenth New Jersey Volunteer Infantry during the Civil War; died at his home in Philadelphia. June 25, aged 66.

John S. Sullivan, M.D. Atlanta (Ga.) Medical College, 1891; a member of the American Medical Association. and one of the best known practitioners of Macon, Ga.; died at his home in that city, June 22, after an illness of several months, aged 58.

Henry Morris Raker, M.D. Jefferson Medical College, Philadelphia, 1862; of Augustaville, Pa.; died in the Mary H. Packer Hospital, Milton, Pa., June 19. from cerebral hemorrhage, after an illness of sevral days, aged 67.

James S. McNeel, M.D. Rush Medical College, Chicago, 1889; a member of the State Medical Society of Wisconsin; died at his home in Waterloo, June 20, from cerebral hemorrhage, after an illness of several days, aged 67.

James A. Lydston, M.D. Rush Medical College, Chicago, 1885; formerly professor of chemistry in the College of Physicians and Surgeons; died suddenly at his home in Chicago, July 6, from the effects of the heat, aged 47.

William Glasgow Condit, M.D. Chicago Homeopathic Medical College, 1900; Jefferson Medical College, Philadelphia, Pa., 1904; a member of the Iowa State Medical Society; died at his home in Allerton, June 20, aged 32.

John F. Daniel, M.D. Medical College of the State of South Carolina, Charleston, 1858; died, June 23, at his home in Daniel, Saluda County. S. C., from paralysis, after an illness of three weeks, aged about 75.

Wiliam A. Egbert, M.D. Cleveland University of Medicine and Surgery, 1875; of Spokane, Wash.: died at the Deaconess' Home Hospital in that city, June 23, from heart disease, after a short illness, aged about 65.

Henry Ganter, M.D. University of Würzburg, Germany, 1875; died at his home in Floraville. Ill., from cerebral hemorrhage. June 24, after an illness of three days. aged 59.

Louis H. Reid, M.D. Georgetown University School of Medicine, Washington. D. C., 1876; a Confederate veteran; died at his home in Atlanta, Ga., June 25. aged 68.

Thomas McCausland, M.D. College of Physicians and Surgeons. Ontario, Toronto. 1868; died at his home in Toronto, June 21, after a prolonged illness, aged 72.

George K. Tillotson, M.D. Rush Medical College, Chicago. 1876; of Chicago; died in Lakeside Hospital. July 2, from septicemia, after an illness of two weeks. aged 58.

George F. Webber, M.D. Medical School of Maine. Medical Department of Bowdoin College, Brunswick, 1879; died at his home in Fairfield, Maine, May 11, aged 55.

Oscar T. Lewis, M.D. Medical Department of the University of Tennessee, Nashville, 1891; died at his home in Roans Prairie, Texas, June 23.

Locke S. Pennington, M.D. Memphis (Tenn.) Medical College, 1906; died recently at his home in Steens, Miss.. aged 26.

Deaths Abroad.

M. Bial, M.D., of Kissingen. whose name is connected with researches on the pathology of the metabolism. died at Munich. May 26. aged 38.

A. Reverdin, M.D., the well-known professor of surgery at Geneva. Switzerland. died at that place June 16.

Congenital Obliteration of Esophagus with Report of a Case.

Dr. J. P. Crozer Griffith, and Dr. R. L. Lavenson, Philadelphia, said that they had endeavored to make the report one for reference. and necessarily, they had referred largely to the writings of others, adding such cases as they had collected. The case reported was one of obstruction with fistula into the trachea; a child aged 9 days, admitted to the Hospital of the University of Pennsylvania. had been unable to swallow since birth and every attempt to give anything produced strangulation with cyanosis and regurgitation through the mouth. The child had been greatly emaciated and had died a few hours after admission. A drawing of the condition was shown. Upper part of esophagus ended blindly; lower part opened into trachea. Symptoms were characteristic. There was constant choking over mucus that could not be swallowed. Death invariably occurred in such cases, due partially to drying up of the tissues from lack of water. The only possible thing to do was a gastrostomy, which had been tried in several cases.

Spasmodic Stricture of the Esophagus in an Infant Aged Four Months.

Dr. Samuel S. Adams, Washington, presented the history of infant who came under observation at the age of four months, a year last February. He was called in to see a well nourished baby with a history of having some difficulty in swallowing. The mother had nursed it. he said. up to the third month, when modified milk had to be substituted. The child could swallow at times and then something would take place that prevented swallowing and it would go some days without food. On giving a few spoonfuls of water, which were taken ravenously, distress was shown, with attempts at vomiting. Fluid would come up into the mouth and be swallowed again. After eight or ten attempts it was rejected. together with mucus. Obstruction of esophagus of a spasmodic nature was diagnosed. Attempts to pass a bougie had failed, but a small sound had been passed and followed up with a small feeding tube. Skiagraph showed nothing. The parents had removed the child from hospital and for the next fourteen months it had not been seen, but the condition was said to have persisted. Later the child had died of pneumonia, autopsy showing a pneumonia of posterior left side and rupture of a diverticulum. There was an obstruction of the esophagus due to breaking down of an enlarged tuberculous gland, which pressed upon the esophagus. Below the obstruction there were two diverticuli; and a third above it.

DISCUSSION.

Dr. Augustus Caille, New York. reported a somewhat similar case in a lad of ten, who had had a spasmodic stricture for five years. It came on gradually and the boy was moribund from starvation. Once or twice a week the tube had to be used to feed him. He had had hydrocephalus in infancy and the speaker thought that the irritation was probably of central origin. Dr. Caillé gave a warning regarding the examination of the esophagus by the sound or esophagoscope, having recently seen a girl of 16, with difficulty in swallowing, examined with the esophagoscope by expert, who had run the instrument into the pleural cavity. which was followed by pneumothorax and death.

Dr. C. B. Putnam, Boston, mentioned a case like Dr. Griffith's. that had occurred in a child 3 years of age. The esophagus had had a blind ending and the lower portion had opened into the trachea.

Dr. Thomas Morgan Rotch, Boston, said that some of these cases of constriction of the esophagus simulated very closely pyloric stenosis and were almost identical as to rational signs. There was danger in passing a sound because there seemed to be a thinning of the wall at the lower part of the esophagus in these cases. They also simulated closely cases of chronic gastric indigestion.

Dr. A. Jacobi, New York, said that carcinoma of the esophagus was apt to be found in the same position. He thought that the cause must be looked for in embryonal conditions. Defects of the muscular layers were quite common.

Dr. Samuel S. Adams, Washington, said that there had been no fluid found outside the esophagus in the surrounding tissue, nor had there been anything in the bronchial tubes, but he believed the pneumonia to have been probably the result of inspiration of some food the child had been trying to take.

A Simple Method of Circumcision in the Newborn.

Dr. W. Reynolds Wilson, Philadelphia, said that the disadvantages of the usual method were, first, in the incompleteness of removal of the foreskin in instances where it was adherent to the glans; second, in the application of the sutures; it might require a number of sutures to control the bleeding points and the sutures thus placed irregularly might have to be tightened to the point of unduly constricting the tissues, as a result of which edema might occur; should sutures become infected, a slough would form and resulting granulations would be difficult to deal with. He splits the prepuce longitudinally on the dorsal aspect with a pair of sharp scissors. The skin was first divided, division of the mucous membrane to a point corresponding to the limit of division of the skin following. The mucous membrane was rolled back to the corona and rendered perfectly free. The scissors were used to trim off the redundant fold of skin and mucous membrane on either side of the incision, and the redundant fold of skin to the distal side of the frenum was likewise removed. The skin was then drawn back and carefully inspected, in order to deal with any irregularity in the cut edge. A tape of gauze, half an inch in width, and so cut that the edges were frayed was applied, securing the roll of mucous membrane in position behind the corona and compressing the bleeding vessels. The end of the glans was left uncovered so that there might be no obstruction to the meatus. Over the gauze tape a dry gauze pad was placed and the napkin applied.

Acute Epidemic Anterior Poliomyelitis.

Dr. Henry Koplik, New York, said the epidemic which had visited New York last summer had been the most extensive known in New York and possibly in the United States, numbering something over 1,200 cases; and his impression was that a great many were not reported to the Board of Health. The disease had been quite widely distributed; it had occurred, not only in the crowded or filthy districts, but in the best localities. Conditions of the streets had not been unusual; there had been nothing in the water supply to attract attention, and the milk supply had been as good as in previous summers. The general characteristics of the disease had not resembled that which was known as poliomyelitis anterior, but something new. There had been cerebral cases, in which the child apparently healthy would go into a sudden condition of unconsciousness, or develop paralysis of the extremities, with difficulty in respiration and swallowing In other cases the cerebral condition would abate but there would be complete paralysis. The child might go to bed apparently well and wake with acute pain in the extremities and joints. These cases were often mistaken for rheumatism. Patients would go to bed well and awake with paralysis of the extremities. The term poliomyelitis must be accepted temporarily. In the majority of the neurotic cases the reflexes had been increased. The rapid atrophy of the muscles in the cases where paralysis was to remain permanent had been striking. As to mode of infection; in most there had been some history of intestinal disturbance; in others a distinct tonsillar inflammation just before the onset of the disease. There was a new infectious agent capable of causing paralysis and even death by its effect on the gray matter. It was sad to see how many children had been incapacitated by this disease. The treatment which had seemed to give the best result was that pursued in other forms of neuritis—hot baths, massage, electricity, etc. Dr. Koplik advised keeping up the tone of the muscle while the paralysis lasted.

Early Symptoms of the Recent Epidemic of Poliomyelitis.

Dr. L. E. LaFetra, New York, said that the epidemic in New York did not agree with the ordinary symptoms of poliomyelitis, which begun with vomiting and fever, followed later by paralysis. He had made a study of the early symptoms in 63 cases. The condition preceding the onset of the disease had not been sufficiently uniform to justify any conclusion. Vomiting had occurred in 25 cases; constipation in 14; diarrhea in 17. Fever had been noted as present in 52, but probably had been present in all. Restlessness and irritability had been very common. In three cases there had been marked general hyperesthesia; convulsions in 4, but severe in only 1; rigidity of the neck in 11, persisting over a week in one. Study of the reflexes was not satisfactory; of 20 cases reflexes had been absent in 16. In 2 patellar reflex had been absent on both sides while paralysis had involved only one extremity. In no case had the tendon reflex been exaggerated. Babinski sign present in 3. Apathy present in 10 cases, stupor in 4 cases, headache noted as present in 10 cases; photophobia present in 3. Pain and tenderness in the limbs in 3. Character of the paralysis: in 58 cases flaccid, in 5 rigidity. Opisthotonos had existed five days in one case. Lumbar puncture had been done in 14 cases; fluid clear in every instance and negative as to bacteria. Confusion with meningitis or neurosis very easy in the early stage.

DISCUSSION.

Dr. L. Emmett Holt, New York, said the epidemic was now being studied by a committee appointed by several of the societies, and according to the best information obtained the number of cases in New York was not far from 3,000, so that it was probably the largest epidemic in the world. He had been struck by the number of groups of cases occurring together.

Another striking thing was the number of cases that recovered, and completely. The disease had stopped with the advent of October and that had been the history of these epidemics everywhere—that they ceased with the beginning of cold weather. Examinations suggested that it was perhaps an acute inflammation of the central nervous system, which generally localized its effects on the anterior horns, but might affect the cerebrum without affecting the cord at all.

Dr. A. Jacobi, New York, did not agree with the view that it was an entirely new disease. He thought that it was not perhaps a disease of the cord itself, but of the whole nervous system. Similar cases had been observed in the extensive reports of Heine, in 1840 and 1860. Cases of polioencephalitis had a greater tendency to get well than cases of poliomyelitis.

Dr. John Lovett Morse, Boston, agreed that the symptomatology in this epidemic was not new.

Dr. C. G. Kerley, New York, had seen in this epidemic 43 cases, 13 in the Babies' Hospital, 9 in other institutions, 3 in his own practice and 18 in consultation. He agreed with Dr. Koplik and Dr. LaFetra as to the symptomatology.

Dr. Henry Koplik, New York, said that the findings postmortem in two fatal cases at the Mount Sinai Hospital showed areas of softening throughout the cortex; areas of hemorrhage throughout the cord, and areas of softening in the cord. The disease did not affect any other nervous disease that might be in progress at the same time.

An Unusual Type of Acute Nephritis in Children.

Dr. John Lovett Morse, Boston, said that he had recently seen a number of cases of acute nephritis in children in which the characteristics of the urine had been materially different from those of the ordinary form, the chief difference being the complete or almost complete absence of blood and blood elements and the presence of a large number of small, round, mononuclear leucocytes. There could be no doubt that the cases were acute and not chronic. The course was essentially the same as in other forms of acute nephritis with the exception that the duration was usually shorter and the prognosis somewhat better. The histories were given in detail and illustrated the types very well In some instances not only was blood absent but very few other renal elements were found even when the symptoms were marked and there was a large amount of albumin. The only description which seemed to fit this type was one by Huenner He thought the condition one of pyelonephritis rather than the ordinary acute glomerular or interstitial nephritis.

DISCUSSION.

Dr Henry Koplik, New York, called attention to the description in Osler's collection of cases of typhoid with the occurrence of such kidney trouble in which there were leucocytes and casts in the urine He had a case then under observation in which the existing nephritis probably resulted from gastro enteritis

Dr J H Mason Knox, Baltimore, described similar cases running a chronic course in which sections showed convoluted tubules undergoing hyaline degeneration, the nuclei not staining at all

Dr L E LaFetra, New York had had one case that corresponded quite closely with those of Dr. Morse, and in that case the leucocytes had persisted for a long time after disappearance of the casts The child had been otherwise in good health and the only thing that had called attention to the condition had beeen some puffiness of the eyelids

President's Address—Public School Education

Dr Charles Gilmore Kerley, New York, said that the education of a child, taken in a broad sense comprehended all that disciplined and enlightened the understanding, cultivated the taste and formed manners and habits It meant all preparation all means to the end of fitting the child for a field of activity whereby his own life might be made more satisfactory to himself and more useful to the state The child should be taught how to live

Dr Kerley considered the subject from the two standpoints That which related to the child's physical, and that which related to its mental development The speaker said that in the United States to day there were 18,000,000 children in attendance at the public schools The school year had been increased from three months to ten months The chief control of the child had been transferred from the home to the school, which meant that the duties and responsibilities of the public school had increased tremendously He quoted from the report of Dr Maxwell, Superintendent of Schools in New York, who said "sitting several hours a day at a desk which may not be hygienically constructed, increases such diseases as curvature of the spine and often produces faults of posture, and defects in eyesight " Dr Kerley advocated some changes in the curriculum He would have the pupils taught reading, penmanship, geography, history and arithmetic and leave out the non essentials Among the essentials he included religion, as it was the corner stone of character, it should comprise allegiance to a Supreme Being and obligation to one's self and his neighbor Social prophylaxis should be taught and what constitutes morality The pupil should be taught the deleterious effects of alcohol and narcotics Dr Kerley deprecated the system of prizes and rewards for the best recitations and sets of answers as a bad one, as it overtaxed the pupil He would impress on teachers and the Boards of Education the thought that 'labor is the inevitable lot of the majority and the best education is that which makes labor the most productive"

Recent Diagnostic Methods in Tuberculosis of Children

Dr L Emmett Holt, New York, presented this paper, which consisted principally in the exhibition of a series of charts illustrating the employment of the fever reactions to tuberculin, the tuberculin eye test (Calmette) and the tuberculin skin test (v Pirquet) Of the fever reactions to tuberculin, he said, of the positively tuberculous, 22 were positive, 1 doubtful and 1 negative, of cases probably tuberculous there were 17 positive reactions no doubtful or negative of cases probably not tuberculous 2 positive reactions, of the positively not tuberculous, 1 positive, 60 negative reactions There had been no unfortunate results in any of the cases, 568 tests had been made The second chart was based on experiments with the Calmette test of the positively tuberculous there had been a positive reaction in 24, doubtful 3 negative 8, probably tuberculous, 15 positive, 1 doubtful, probably not tuberculous, positive 2, doubtful 6, negative 508 Tuberculin skin test, of the positively tuberculous, positive 7, negative 1, probably tuberculous, positive 9, negative 1 probably not tuberculous, negative 41, positively not tuberculous negative 3 In the skin test there had been no doubtful reactions recorded, a point in favor of that test He had not employed the Moro test, with inunction As regarded reliability, the fever test was not so scientific The skin test was made with three scratches and 25 per cent tuberculin rubbed into two of them The character of the reaction was definite The skin and temperature tests were the most reliable, and absolutely free from risk Experience of others had shown that eyetest was not altogether free from risk He thought the fever reaction would disappear from clinical use to be replaced by the other two tests In regard to ease of application the skin and Moro tests were to be preferred The eye test also was satisfactory in this respect He considered the tests of great assistance in the diagnosis of tuberculosis

DISCUSSION

Dr William P Northrup New York agreed with the essayist He did not take a cheerful view of the injection test, He thought there was considerable risk in the eye test

Dr Thomas Morgan Rotch, Boston, agreed that the fever test would not be so popular in the future as the eye and skin tests, but they had never met with any serious results except where there had been a fault in the technic In 100 consecutive cases the eye test had given no bad results He preferred the skin test

Dr Augustus Caille New York, opposed the eye test, as he did not think the eye a proper organ for experimentation He thought it fairly unreliable

Dr Henry Koplik New York had found the v Pirquet test useful in those cases where fever existed and the tuberculin fever test was ruled out The eye test he had not allowed to be used in his service as he was afraid of it

Dr S M Hamill, Philadelphia had ruled out the eye test because it produced a lesion which was painful and disturbing, and he considered that it was attended with some risk

Dr A H Wentworth, Boston called attention to the positive reactions in healthy persons and said that there were a good many tables published in German literature of apparently healthy persons giving positive reactions In one series one sixth gave a positive reaction for the eye test and almost one half for the cutaneous

Dr L Emmett Holt, New York said that positive reactions in healthy persons might be due to latent tuberculosis

Fresh Air in the Treatment of Disease

Dr William P Northrup New York presented two points, one as to the practical application of open air treatment the other as to the cases to which it is adapted One of the first questions he said, was Is cold essential? He was convinced that it was The experience of the Health Department of New York in the treatment of tuberculosis was interesting patients put out in the open shack slept well without "dope He considered this one of the most important points—that the patients became quiet and slept One of the first rules should be that the patient and attendant should be made comfortable, and this could be done in very cold weather if gone about in the proper manner As to the preparation of the bed there should be first laid upon a spring mattress a sufficiently large blanket that when folded over should represent an envelope, it should be brought over and pinned around the entire patient inside this there should be a paper or rubber layer to keep the cold from coming up from below The patient should be clothed in a union suit With adults it might be necessary to wheel them inside once in a while to allow them to stretch As to the type of disease adapted for the open air treatment he suggested pneumonia scarlet fever, measles, bronchitis acute febrile disease of any kind As to the results it killed nobody, it hurt nobody, and he was equally sure that it helped all. In doubtful, desperate cases it had often determined the balance in favor of cure.

Dr. E. E. Graham, Philadelphia, said that the fresh air treatment had been of prime importance in reducing the infant mortality in his institutional practice. He had lost his dread of pneumonia as a hospital disease since the beginning of this manner of treatment in the wards. Typhoid patients did so much better in the fresh air that nothing could induce him to return to the old treatment.

AMERICAN ASSOCIATION FOR CANCER RESEARCH.

Meeting held in Buffalo, April 15, 1908, at the New York State Cancer Laboratory.

The President, Dr. James Ewing, New York, in the Chair.

Hemolytic Tests for Malignancy in Human Beings.

Dr. George W. Crile reported the results of the test as follows:

I. Normals. 107 tests. No hemolysis.

Tests of miscellaneous diseases, 50. Hemolyzed, 4. These 4 included 1 hemoglobinuria, 1 eclampsia, 1 gastric case diagnosis not made, and 1 hematuria. Carcinoma, 50. Hemolyzed, 39. Sarcoma, 16. Hemolyzed, 13. Making a total of 66 cases of malignancy in which 53 hemolyzed.

Carcinoma recurrence, or cured, to prove if cured. Ten tests made, 9 no hemolysis, 1 questionable. Papilloma, 2 tests. Hemolysis, 1; no hemolysis, 1. Tuberculosis (surgical), 11 tests; hemolyzed, 9. Chronic suppuration, 10 cases. No hemolysis.

II. Of the 13 cases not giving hemolytic reaction: One gastric case: diagnosis not proved. One sarcoma spine; advanced case. One suspected sarcoma; advanced case. One carcinoma recurrence; advanced case. One cystic ovary. Five carcinomata breast; advanced cases. Two epitheliomata (neck); advanced cases. One lymphosarcoma; advanced case.

Suspected malignant cases not showing hemolysis, and positive diagnosis proving no malignancy: Two gastric cases. Four gall-bladder cases. Two tumor of the thigh. Two cirrhosis of liver. One tumor of chin. One tumor of clavicle. One cystic ovary. One breast case (cyst).

Case on the medical service March 18, 1908, showed hemolysis and reverse hemolysis, and a tentative diagnosis of carcinoma of the stomach was made. Medical service diagnosed the case anemia. April 25 medical service palpated tumor and diagnosis of carcinoma of stomach was made from specimen of tissue from stomach contents.

DISCUSSION.

Dr. R. Weil, in discussing Dr. Crile's paper, staid that during the past few years a number of observers had studied the hemolytic effects of human serum in certain diseases. The majority had used the corpuscles of alien species, but some, notably, Ascoli, had used human corpuscles. Ascoli had, by this method, reported three cases of hemolysis by cancer sera, but had also found hemolysis in other diseases. Dr. Weil had some time ago reported the results of a systematic study of the effects of a series of sera derived from dogs suffering with tumors, on the corpuscles of other dogs suffering with the same disease. He had found these sera hemolytic in almost every case, but he had also found normal sera frequently hemolytic for dog corpuscles. He had, however, been able to demonstrate a specific resistance on the part of the corpuscles of tumor dogs to the serum from such animals, which normal corpuscles do not show. He was glad that Dr. Crile had been able to confirm these reactions in human beings. His own experience in a smaller number of human cases had failed to reveal any such specific corpuscular resistance in cancer cases. He believed that the serum in human cancer is sometimes hemolytic, often not so, and that other diseases, such as tuberculosis, often show the same conditions. He did not believe that the reaction in human beings is of any value at present. The specific resistance of red cells to the hemolytic sera of the individuals from which they were derived is a phemonenon which needs much further study. It has been demonstrated as the result of the injection of eel serum in rabbits and has been accepted by Ehrlich. It seems to be a necessary corollary of the existence of isolysins, as demonstrated by Theobald Smith in horses, and by the speaker in dogs, but was far from being generally accepted or understood.

The Lymphosarcoma of Dogs.

Dr. Leo Loeb reported on investigations carried out with Drs. John Hunter and G. M. Laws into the character of the lymphosarcoma of dogs. About eight years ago the author showed that after a successful inoculation of the sarcoma of the thyroid of white rats the peripheral parts of the transplanted cells remain alive and multiply rapidly by mitotic division. The new sarcomata arise through a proliferation of the transplanted tissue and through cell multiplication in the host. Afterwards Jensen showed the same process to take place after transplantation of adeno-carcinomata of the mouse. In regard to the tumors found in dogs in the genital region, opinions differ very much. Sticker maintained that the inoculated tumors originate through a multiplication of the transplanted cells. Bashford disputed this view and stated that the formation of the new growths results from an infection of the host by unknown organisms. Beebe and Ewing showed that after transplantation the peripheral tumor cells remain alive and give origin to the tumors, a view which has not yet found general recognition. The author's investigations show without any doubt that the interpretation of Sticker and Beebe and Ewing is correct. The examination of tumor pieces at different periods after transplantation proves that peripheral tumor cells remain alive and propagate very soon after inoculation. That at any stages the connective tissue cells of the host can be proved to participate in the proliferation, as has been recently maintained by Wade, is very unlikely, but further researches into this question will be made.

The Transplantation of Skin of the Guinea-Pig into Different Species.

Dr. Leo Loeb and Dr. W. H. F. Addison said that a very large number of comparative transplantations of guinea-pig skin into the guinea-pig, rabbit, dog, pigeon and frog showed that (1) after transplantation into the rabbit and dog, infection of the transplanted skin is much more frequent than after transplantation into the guinea-pig and pigeon. (2) The number of pieces which grow is very much smaller after transplantation into foreign species. (3) Pieces of guinea-pig skin can proliferate by mitotic division in the rabbit and dog up to 8 days; but such a proliferation is only exceptional in the dog; in the pigeon such a proliferation may take place up to the sixth day and is much more frequent. No mitosis can be seen in the frog at any period after transplantation: the skin dies very rapidly in the frog; if such skin is retransplanted into the guinea-pig about six hours after transplantation into the frog, no growth takes place in the guinea-pig. Living epithelium is seen in the rabbit even ten days after transplantation. (4) Pieces of guinea-pig skin which remain alive in the rabbit are destroyed through the proliferation of the surrounding connective tissue of the host, in a similar way as guinea-pig skin transplanted into the guinea-pig is gradually destroyed through the surrounding connective tissue, in cases in which the epithelium of the guinea-pig skin has not been able to form a cyst. The formation of such a cyst has never been observed in the author's experiments, after transplantation of skin into other species, because the energy of cell-growth is less under these conditions. (5) They find typical differences in the curve of growth after transplantation of skin into different species. In the frog no growth takes place. In the pigeon the cell proliferation in the first five days is very good, but then follows a sudden decline. In the rabbit the growth of the non-infected pieces is in the first five days not better than in the pigeon, but, after this period the rabbit forms a soil much superior to the pigeon. In the dog the growth is usually very slight. On the whole, therefore, there is a distinct connection between the condition of growth of the transplanted skin and the relationship between the guinea pig and the animal into which the skin has been transplanted (b) The facts established can not be very well explained on the basis of Ehrlich s hypothesis of athreptic immunity, but suggest the presence of toxic substances in the organisms of a different species

Dr Leo Loeb demonstrated microscopic specimens of different varieties of malignant struma, sent by Professor Langhans from the Pathological Institute in Berne

Autoinoculation or Local Infectivity of Cancer.

Dr William B Coley, of New York, read this paper and gave a report of cases Regarding the question of autoinoculation of lip carcinoma, Dr Coley referred to an important discussion on this subject in Glasgow 20 years ago, in which Sir Hector Cameron expressed his opinion against autoinoculation In this discussion Cameron stated that 'the upper lip in every case of epithelioma of the lower lip, is in close contact with the disease, night and day. But, has any one ever seen the upper lip become infected by direct contamination under such circumstances?"

Dr Coley then cited Butlin, who stated that, since this discussion took place, there have been three cases of infection of the upper lip by the lower, but in only one—that of v Bergmann, had a microscopical examination been made of both tumors Through the kindness of Dr George C Johnston, of Pittsburg, Pa, Dr *Coley was enabled to report another case* of apparent autoinoculation of the upper lip from an epithelioma of the lower lip The patient, male, age 47 years, consulted Dr Johnston in the fall of 1904, with a typical carcinoma of the lower lip involving the submaxillary glands Refusing operation, the patient was treated with the *x* ray, with the result that the tumors disappeared Three years later, there developed a similar, typical, epitheliomatous tumor on the upper lip, precisely over the site occupied by the tumor of the lower lip three years before Dr Coley presented photographs of the case taken at different periods during the three years He believed that from this observation it would be difficult to escape the conclusion that the tumor of the upper lip was the result of direct contact infection from the tumor of the lower lip, and, furthermore, that there was an incubation period of three years, which makes the case unique

Dr Coley reported in brief another case which had been under his personal observation about eight years ago in which a primary carcinoma of the cecum had caused a similar tumor to develop in a loop of small intestine by direct contact infection He had performed resection of both the large and the small intestine, and microscopical examination showed the growths to be of similar type in both cases He stated that he had also observed a number of the more common varieties of so called autoinoculation, e g, rapidly developing carcinoma of the muscle and skin wound of the abdomen, following operation for abdominal carcinoma, especially in cases in which free fluid was present at the time of operation

He referred to a recent paper by Charles Ryall (*Lancet*, Nov 9 1907) on Cancer Infection, describing 25 personal cases illustrating the various types of autoinoculation

Dr Coley stated that he believed the local infectivity of cancer to be an indisputable fact which no one, who has had a large operative and clinical experience with the disease can doubt He believed that if this fact were more generally appreciated, it would lead to much greater care in cutting wide of infected areas at primary operations, and would greatly lessen the number of so called palliative operations for cancer, in which the disease is but partially removed and in which highly infective cancer cells are widely disseminated over new areas

DISCUSSION

Dr Leo Loeb, in connection with Dr Coley s interesting observations, mentioned (1) that in the course of his transplantation of various sarcomata in the white rat he had observed a number of cases in which tumors developed as the result of contact of tumor cells with certain tissues Especially noteworthy was the fact that tumors of similar structures differed widely in regard to the readiness with which contact metastases could be produced Rapidly growing strains of sarcoma caused the formation of contact metastases much more frequently than slowly growing strains although the microscopical structure in both cases was almost identical This fact is not without interest to the operating surgeon (2) In a paper recently published in the *Journal of Medical Research*, he showed with Dr S Leopold, that tumor inoculation into the same organisms in which the tumor originated might succeed, while inoculations into other individuals of the same species were unsuccessful and he pointed out that the same probably holds good for the majority of tumors, including tumors in man For that reason contact metastases may still be produced, where inoculation into another individual would be unsuccessful

Dr Coley stated that it was possible that the tissues of an individual suffering from cancer, were more liable to infection from cancerous material, than in a healthy individual This would seem to be shown by the very small number of cases in which the surgeon has apparently been infected during operation on cancerous patients

The cases which he himself reported together with the 25 cases reported by Ryall, certainly prove beyond any question that the cancerous cells have the power of autoinoculation, at least in individuals suffering from cancer That this infection has the power of remaining latent for very long periods of time, is shown by his own experience in cases of late recurrence of cancer of the breast He stated that he had observed three cases *in which local recurrence had taken place within* periods of from 12 to 17 years after operation At the meeting of the American Surgical Association, a year ago one case of local recurrence 20 years after operation was reported

Dr Coley further stated that, naturally, the question arises whether the cancer cell itself remains alive and dormant all these years, or whether it is a micro organism of some sort which, as in tuberculosis, remains latent for long periods In view of the recent observations of Ehrlich and Loeb showing that it is possible for a carcinomatous tumor in animals to be transformed, in a single generation, into a sarcomatous tumor, there is some ground for accepting the theory of Ballonce of London, who believes that a single micro organism may, under varying conditions, give rise to proliferation of epithelial cells at one time and connective tissue at another time

AMERICAN ASSOCIATION OF GENITOURINARY SURGEONS

Twenty second Annual Meeting, held at Hot Springs Va, May 1 2, 1908

The President, Dr Harvey G Mudd, St Louis, in the Chair

Cases of Stricture of the Membranous Urethra

Dr Edward L Keyes Jr, New York, said that up to the end of the last century gonorrheal stricture was considered to be confined to the anterior urethra By performing perineal prostatectomy surgeons have come to recognize strictures at the neck of the bladder, but, with the exception of the case reported by Bazy, attention has not been called to strictures of the membranous urethra, and that portion of the urethra now enjoys the distinction of being the one portion of that canal supposedly exempt from sclerotic infiltration It is supplied with the glands of Littré, and therefore offers a good field for that gonococcal penetration into the tissues which is the foundation of gonorrheal stricture Dr Keyes reported in detail two cases recently operated on, in which there was very marked stricture of the membranous urethra In the first case perineal section was performed with a guide and under cocain The urethra being opened a probe readily entered the membranous urethra and this was cut on widely for about an inch—almost to the apex of the prostate—but even at this point nothing larger than a grooved director would enter the urethra The second case was one of dense stricture in the bulbous urethra extending into the membranous urethra This portion of the canal would take nothing larger than a 10 F bougie These two cases suggest that ancient neglected strictures of the bulbous urethra may often involve the membranous urethra as well The presence of stricture in the mem branous urethra appears to add no danger or symptoms to that of the bulbous urethra. A more frequent use of local anesthesia will probably disclose the frequency of this condition.

DISCUSSION.

Dr. Hugh H Young, Baltimore, said he thought that back of the posterior layer of the triangular ligament it is rare, indeed, to find any stricture, but that that portion within the triangular ligament is more commonly involved, and he has seen two or three cases in which that was the condition

Dr Bransford Lewis, St Louis, said he had met with stricture not only of the membranous urethra, but also distributed along the prostatic urethra, or both

Dr Samuel Alexander, New York, said he thought that we need not alter the generally accepted opinion that strictures of the urethra are in nearly all cases primarily limited to the anterior portion of the urethra; but the fact that strictures, not traumatic, of the membranous urethra do occur secondarily to stricture of the anterior portion of the urethra, has been well recognized for some time Primarily there is a stricture of the anterior urethra, above that a dilatation of the membranous urethra, followed by infection of the glands of Littré, and then a secondary contraction of the membranous urethra. These strictures are always secondary to strictures of the anterior urethra, and due to a periurethral inflammation about the membranous urethra

Dr James Pedersen, New York, said his teaching had been that strictures of the membranous urethra do occur, and he asked if Dr. Keyes did not mean to present these cases merely as exaggerations of cases of stricture of the membranous urethra

Dr Keyes said his teaching had been that strictures of the membranous urethra were solely traumatic and not gonorrheal. Until he heard Dr Young's remarks, the only case reported that had been submitted to proof was the one reported by Bazy Mild stricture of the membranous urethra probably occurs very frequently

Common Errors in the Treatment of the Urethra and Bladder.

Dr James Pedersen, New York, said that, excluding errors of judgment, errors in diagnosis and the accidents of normal instrumentation, there remains a high percentage of urethral and bladder cases which have been over-treated or erroneously treated by a conscientious physician who, all unwittingly, has thus fallen short of the attainable. The common errors in the treatment of the urethra and bladder may be classed under two heads—errors of omission and errors of commission. Under errors of omission may be grouped: Neglect of a prostatitis or seminal vesiculitis or both; neglect of the patients' general condition; failure to insist on sexual hygiene; failure to regulate his habits as to alcoholics, tobacco and coffee; inattention to the dietary and the quantity of water drunk. Under errors of commission may be placed: The use of the sound in the face of contraindications; over-frequent dilatation and overdilatation; the unscientific use of irrigations in general; in particular, the use of intravesical irrigations before the chronic stage of a urethritis; the use of strong—that is, caustic, injections and instillations; the sudden emptying of a chronically overdistended bladder; the administration of methylene blue except as a placebo; and, finally, the use of undistilled water in making up solutions of silver nitrate. Numerous illustrative cases were cited.

Congenital Abnormalities of the Penis and Their Influence on the Acquisition and Course of Gonorrhea.

Dr E. Wood Ruggles, Rochester, N. Y., considered the various congenital abnormalities of the penis in detail, and mentioned illustrative cases This, more than any other organ of the human body, is subject to the most varied changes in development and in appearance.

Disturbances Due to Disease of the Verumontanum and Its Treatment with the Posterior Urethroscope.

Dr. George K. Swinburne, New York, described the symptoms due to disease of the verumontanum, presented his posterior urethroscope for treating such conditions, and went into detail regarding the treatment. He uses silver nitrate, 10 per cent., or argentamin, full strength. Applications are made not oftener than once a week. Work on the posterior urethra through the urethroscope during the past eight or nine years has convinced him that it is a valuable aid and a distinct advance in the treatment of trouble in that portion of the genitourinary tract, and that many obscure symptoms may be found to be due to disease or to some pathologic condition of the verumontanum, or of the urethral floor in its immediate vicinity. He prefers the instrument with the Koch auxiliary chamber because it keeps the lamp out of the way while swabbing the mucous membrane.

Operative Treatment of Tumors of the Bladder.

Dr. Louis E. Schmidt, Chicago, said that since he presented his paper last year he had had eleven cases of tumor of the bladder, four of which had come to operation. In those four he had carried out the precepts laid down in the former paper, and he sees no reason to change the conclusions set forth in that paper. These are: (1) All benign tumors of the bladder should be approached from the inside of the bladder, and all malignant tumors from the outside. (2) In all malignant cases in which the loss of substance is not too great, the bladder should be closed completely by sutures after the removal of the tumor. (3) In cases of malignant tumor the incision into the bladder should be made in accordance with the location of the growth as defined by the cystoscope. (4) The permanent catheter should be abolished. (5) Gas anesthesia should be employed exclusively. (6) A subsequent cystoscopic surveillance should be maintained over any bladder that has been operated on for tumor.

Fatal Case after 128 Successful Perineal Prostatectomies.

Dr. Hugh H. Young, Baltimore, gave the details in this case and showed the kidneys, ureters and bladder. He said that the point he wished to emphasize was that there are certain cases that should not be operated on at once, particularly cases that have not been catheterized, although the urine may be of good quality when first examined. In these cases there is apt to be anuria or marked disturbance in the function of the kidneys, because they will not secrete so fast as they do when working against pressure. When the pressure is removed, a kidney which has been working against pressure for years will stop working.

Urethrorectal Fistulas.

Dr. Samuel Alexander, New York, read a paper on: (a) "An Operative Device for Urethrorectal Fistulas, (b) The Restoration of Voluntary Control of the Urogenital Sphincter in Incontinence of Urine Following Operations on the Prostate." He operates on urethrorectal fistulas as follows: A curved incision is made in front of the anus, extending from one tuberosity of the ischium to the other; the central portion of the perineum is divided and the dissection is carried upward between the rectum and the prostate, so as to expose the wall of the rectum externally for at least one-half inch above the upper margin of the fistula; the edges of the fistula are separated from the urethra by cutting with a sharp knife and scissors; the edges of the urethra at the seat of the fistula are carefully freshened, but the urethra should not be sutured. the tissues about the fistulous opening in the rectal wall are then freshened with curved scissors and made smooth; the opening in the rectal wall is closed by interrupted Lembert sutures of chromicised catgut placed from the perineal side: the sutures should not include the mucous membrane of the bowel. To protect the line of suture in the rectal wall, the following expedient is used: A small triangle of gauze consisting of six or eight layers is made to fit the wound. The apex of this triangle is carried by forceps into the vesical orifice. Between the layers of gauze a 10 per cent. iodoform ointment, made with petrolatum, is then injected from a glass syringe between the layers of the gauze, and the little pad is then plastered down so as to fit the posterior surface of the perineal wound accurately.

In restoring voluntary control the principle of treatment is to make the individual learn by practice to exercise voluntary control over what remains of the urogenital sphincter, thus preventing the escape of urine. If this can be done, automatic control follows as a physiologic necessity. Any atonic or damaged muscle may be made to act, and the power of its action gradually increased by proper exercises.

Suture of Urethral and Vesical Sphincters for Incontinence of Urine.

Dr. **Hugh H. Young**, Baltimore, reported this case. The patient had had a perineal urethrotomy performed by another surgeon fifteen months previously, and was suffering from pain and incontinence of urine. Local treatment by massage of the prostate and dilatation of the urethra made him worse. It was evident that in the previous operation both sphincters had been divided. Preliminary suprapubic cystotomy showed the vesical sphincter to be gaping, so that the index finger could be easily introduced. After excising the mucous membrane in the lower half, the ends of the muscle were caught with tenaculum forceps and drawn together with catgut sutures. A large mass of scar tissue was found in the perineum, and a considerable portion of this was excised on each side, along with some urethral mucous membrane. The dissection was carried well out on each side until healthy looking muscle was reached, and the ends of the muscle were approximated with catgut sutures and the wound closed. Both suprapubic and perineal drainage were provided for, the latter by means of a small catheter which emerged from the anterior angle of the wound in the bulbous urethra. The convalescence was satisfactory, and although it has been necessary to dilate for stricture at the site of the operation, yet the patient has regained perfect control over his sphincters.

Antigonococcic Serum.

Dr. **George K. Swinburne**, New York, read this paper. Since June, 1906, he has used the serum almost without interruption on a large variety of cases. Since September, 1907, he has treated 69 cases, 41 dispensary and 28 private cases. The serum was used in 14 cases of chronic relapsing epididymitis, 10 of which were dispensary cases, and in almost all there was marked improvement. The striking relief noted was in the diminution or quick cessation of the pain. In the cases of acute epididymitis, 27 in all, the majority were relieved of pain within forty-eight hours, and almost all went on to uninterrupted recovery. There were 4 cases of muscular rheumatism in connection with chronic gonorrheal disease treated with the serum. Two were relieved and 2 received no apparent benefit. There were 10 cases in which there was muscular rheumatism with apparent involvement of one or more joints. The majority of these yielded promptly, 1 was not relieved, and 2 were but slightly improved. Five cases of pure joint lesions were treated, and responded promptly to the serum. They all followed a primary attack of gonorrhea. In 2 cases of gonorrheal kidney in which the serum was used there was no improvement. Though the serum is supposed to have no power over the gonococcus, yet in 2 cases of persistent presence of gonococci in the urethral discharge the organisms disappeared after the use of the serum. In 1 case of acute prostatitis in which the serum was used once a day for three days, there was relief of the pain and throbbing. It was used in 1 case of acute vesiculitis with immediate benefit.

DISCUSSION.

Dr. **Louis E. Schmidt**, Chicago, has used the serum treatment in a number of cases of prostatitis and epididymitis, and has noted all kinds of complications during the course of the serum treatment with no benefit whatever.

Operative Treatment of Acute Gonorrheal Epididymitis.

Dr. **Francis R. Hagner**, Washington, gave a further report. He published his original paper in the *Medical Record*, Oct. 13, 1906. The operative treatment of gonorrheal arthritis was the procedure that suggested operative intervention in these cases. In every case operated on fluid had been present in the tunica vaginalis, varying in amount from two drams to two ounces. This fluid resembled that seen in gonorrheal joints, in that it was usually slightly blood-stained and contained a varying amount of fibrinous material in which are entangled a few leucocytes. The parietal layer of the tunica vaginalis was congested. That portion over the epididymis was intensely so, and seemed to be the seat of small punctate hemorrhages. In a number of cases the entire epididymis was covered with a false membrane. It is the exception if this condition does not exist to some degree. The relief from pain and the rapid absorption of the inflammatory exudate seem to be just as great whether or not pus is obtained. Only the severest cases have been operated on. Since March, 1905, he had operated on but 19 cases, not more than 10 per cent. of the patients of this class. There was but one case that was not relieved absolutely of all pain on recovery from the anesthesia. There was a remarkable difference between the condition of the patients before and after operation. It is interesting to note the fall in the leucocyte count, which in one case dropped from 33,000 to 8,400 in forty-eight hours. There was a parallel fall of the temperature and pulse rate. There had been no cases of infection following the operation, recurrence, atrophy of the testicle, or other distressing sequelæ. In every case the temperature had been lower after operation than before. Pus was present in 17 of the 21 cases, being in the globus minor in 12, in the globus major and minor in 3, in the globus major in 1, and in the tunica vaginalis in 1 case. Of these 21 cases, gonococci were demonstrated five times in the pus from the epididymis, and once from the tunica vaginalis when none could be found in the epididymis. One of the most remarkable effects of this operation is the very rapid disappearance of the induration in both the cord and the epididymis. The wound is usually healed in less than a week. None of the patients have had the hard, nodular condition of the globus minor lasting for a long time, such as persists so frequently in those treated without operation. On an average, the patients are up and about and free from pain in five days. The urethral discharge does not increase afterwards.

DISCUSSION.

Dr. **Samuel Alexander**, New York, said he had employed this operation extensively in the service at Bellevue Hospital, and had achieved very nearly, although not quite, as good results as Dr. Hagner had reported. In five cases of acute epididymitis complicated with prostatic abscess pure cultures of the streptococcus were found.

Dr. **J. H. Cunningham, Jr.**, Boston, has done the operation in six cases, and has observed the same quick relief that Dr. Hagner reports. Some induration remained, however, and in four of the cases the urethral discharge returned.

Other Cases Reported.

Dr. **J. Bentley Squier**, New York, reported some unusual cases; Dr. **van der Poel**, a case of teratoma of the testis; and Dr. **Hugh Cabot**, Boston, the case of a man, 50 years old, in whom varicose veins of a papilla of the kidney were a cause of persistent hematuria.

NEW HAMPSHIRE MEDICAL SOCIETY.

One Hundred and Seventeenth Annual Meeting, held at Concord, May 14-15, 1908.

The President, Dr. **J. H. Neal**, Portsmouth, in the Chair.

Standard Reorganization Adopted.

The House of Delegates had its first meeting the night before the opening of the sessions of the society, with a very creditable attendance. The report of the secretary contained some valuable suggestions, which were referred to a special committee; the committee subsequently recommended an approval of the election of alternate delegates by the component county societies, the publication in one volume of the earlier transactions of the society, and advised the appointment of a committee on the subject of education and the enlightenment of the public on sexual matters and venereal diseases. The last recommendation was laid on the table by the House, and the matter of organization of a branch association, referred by the Secretary of the American Medical Association, was deemed unadvisable at present.

The report of the Committee on Revision of the Constitution, appointed one year ago, read by Dr. Ira J. Prouty, Keene, the Chairman, suggested a number of amendments, the leading one being the adoption of the component county society branous urethra appears to add no danger or symptoms to that of the bulbous urethra. A more frequent use of local anesthesia will probably disclose the frequency of this condition.

DISCUSSION.

Dr. **Hugh H. Young**, Baltimore, said he thought that back of the posterior layer of the triangular ligament it is rare, indeed, to find any stricture, but that that portion within the triangular ligament is more commonly involved, and he has seen two or three cases in which that was the condition.

Dr. **Bransford Lewis**, St. Louis, said he had met with stricture not only of the membranous urethra, but also distributed along the prostatic urethra, or both.

Dr. **Samuel Alexander**, New York, said he thought that we need not alter the generally accepted opinion that strictures of the urethra are in nearly all cases primarily limited to the anterior portion of the urethra; but the fact that strictures, not traumatic, of the membranous urethra do occur secondarily to stricture of the anterior portion of the urethra, has been well recognized for some time. Primarily there is a stricture of the anterior urethra, above that a dilatation of the membranous urethra, followed by infection of the glands of Littré, and then a secondary contraction of the membranous urethra. These strictures are always secondary to strictures of the anterior urethra, and due to a periurethral inflammation about the membranous urethra.

Dr. **James Pedersen**, New York, said his teaching had been that strictures of the membranous urethra do occur, and he asked if Dr. Keyes did not mean to present these cases merely as exaggerations of cases of stricture of the membranous urethra.

Dr. **Keyes** said his teaching had been that strictures of the membranous urethra were solely traumatic and not gonorrheal. Until he heard Dr. Young's remarks, the only case reported that had been submitted to proof was the one reported by Bazy. Mild stricture of the membranous urethra probably occurs very frequently.

Common Errors in the Treatment of the Urethra and Bladder.

Dr. **James Pedersen**, New York, said that, excluding errors of judgment, errors in diagnosis and the accidents of normal instrumentation, there remains a high percentage of urethral and bladder cases which have been over-treated or erroneously treated by a conscientious physician who, all unwittingly, has thus fallen short of the attainable. The common errors in the treatment of the urethra and bladder may be classed under two heads—errors of omission and errors of commission. Under errors of omission may be grouped: Neglect of a prostatitis or seminal vesiculitis or both; neglect of the patients' general condition; failure to insist on sexual hygiene; failure to regulate his habits as to alcoholics, tobacco and coffee; inattention to the dietary and the quantity of water drunk. Under errors of commission may be placed: The use of the sound in the face of contraindications; over-frequent dilatation and overdilatation; the unscientific use of irrigations in general; in particular, the use of intravesical irrigations before the chronic stage of a urethritis; the use of strong—that is, caustic, injections and instillations; the sudden emptying of a chronically overdistended bladder; the administration of methylene blue except as a placebo; and, finally, the use of undistilled water in making up solutions of silver nitrate. Numerous illustrative cases were cited.

Congenital Abnormalities of the Penis and Their Influence on the Acquisition and Course of Gonorrhea.

Dr. **E. Wood Ruggles**, Rochester, N. Y., considered the various congenital abnormalities of the penis in detail, and mentioned illustrative cases. This, more than any other organ of the human body, is subject to the most varied changes in development and in appearance.

Disturbances Due to Disease of the Verumontanum and Its Treatment with the Posterior Urethroscope.

Dr. **George K. Swinburne**, New York, described the symptoms due to disease of the verumontanum, presented his posterior urethroscope for treating such conditions, and went into detail regarding the treatment. He uses silver nitrate, 10 per cent., or *argentamin, full strength. Applications* are made not oftener than once a week. Work on the posterior urethra through the urethroscope during the past eight or nine years has convinced him that it is a valuable aid and a distinct advance in the treatment of trouble in that portion of the genito-urinary tract, and that many obscure symptoms may be found to be due to disease or to some pathologic condition of the verumontanum, or of the urethral floor in its immediate vicinity. He prefers the instrument with the Koch auxiliary chamber because it keeps the lamp out of the way while swabbing the mucous membrane.

Operative Treatment of Tumors of the Bladder.

Dr. **Louis E. Schmidt**, Chicago, said that since he presented his paper last year he had had eleven cases of tumor of the bladder, four of which had come to operation. In those four he had carried out the precepts laid down in the former paper, and he sees no reason to change the conclusions set forth in that paper. These are: (1) All benign tumors of the bladder should be approached from the inside of the bladder, and all malignant tumors from the outside. (2) In all malignant cases in which the loss of substance is not too great, the bladder should be closed completely by sutures after the removal of the tumor. (3) In cases of malignant tumor the incision into the bladder should be made in accordance with the location of the growth as defined by the cystoscope. (4) The permanent catheter should be abolished. (5) Gas anesthesia should be employed exclusively. (6) A subsequent cystoscopic surveillance should be maintained over any bladder that has been operated on for tumor.

Fatal Case after 128 Successful Perineal Prostatectomies.

Dr. **Hugh H. Young**, Baltimore, gave the details in this case and showed the kidneys, ureters and bladder. He said that the point he wished to emphasize was that there are certain cases that should not be operated on at once, particularly cases that have not been catheterized, although the urine may be of good quality when first examined. In these cases there is apt to be anuria or marked disturbance in the function of the kidneys, because they will not secrete so fast as they do when working against pressure. When the pressure is removed, a kidney which has been working against pressure for years will stop working.

Urethrorectal Fistulas.

Dr. **Samuel Alexander**, New York, read a paper on: (a) "An Operative Device for Urethrorectal Fistulas, (b) The Restoration of Voluntary Control of the Urogenital Sphincter in Incontinence of Urine Following Operations on the Prostate." He operates on urethrorectal fistulas as follows: A curved incision is made in front of the anus, extending from one tuberosity of the ischium to the other; the central portion of the perineum is divided and the dissection is carried upward between the rectum and the prostate, so as to expose the wall of the rectum externally for at least one-half inch above the upper margin of the fistula; the edges of the fistula are separated from the urethra by cutting with a sharp knife and scissors; the edges of the urethra at the seat of the fistula are carefully freshened, but the urethra should not be sutured; the tissues about the fistulous opening in the rectal wall are then freshened with curved scissors and made smooth; the opening in the rectal wall is closed by interrupted Lembert sutures of chromicised catgut placed from the perineal side; the sutures should not include the mucous membrane of the bowel. To protect the line of suture in the rectal wall, the following expedient is used: A small triangle of gauze consisting of six or eight layers is made to fit the wound. The apex of this triangle is carried by forceps into the vesical orifice. Between the layers of gauze a 10 per cent. iodoform ointment, made with petrolatum, is then injected from a glass syringe between the layers of the gauze, and the little pad is then plastered down so as to fit the posterior surface of the perineal wound accurately.

In restoring voluntary control the principle of treatment is to make the individual learn by practice to exercise voluntary control over what remains of the urogenital sphincter, thus preventing the escape of urine. If this can be done, automatic control follows as a physiologic necessity. Any atonic or damaged muscle may be made to act, and the power of its action gradually increased by proper exercises.

Suture of Urethral and Vesical Sphincters for Incontinence of Urine.

DR. HUGH H. YOUNG, Baltimore, reported this case. The patient had had a perineal urethrotomy performed by another surgeon fifteen months previously, and was suffering from pain and incontinence of urine. Local treatment by massage of the prostate and dilatation of the urethra made him worse. It was evident that in the previous operation both sphincters had been divided. Preliminary suprapubic cystotomy showed the vesical sphincter to be gaping, so that the index finger could be easily introduced. After excising the mucous membrane in the lower half, the ends of the muscle were caught with tenaculum forceps and drawn together with catgut sutures. A large mass of scar tissue was found in the perineum, and a considerable portion of this was excised on each side, along with some urethral mucous membrane. The dissection was carried well out on each side until healthy looking muscle was reached, and the ends of the muscle were approximated with catgut sutures and the wound closed. Both suprapubic and perineal drainage were provided for, the latter by means of a small catheter which emerged from the anterior angle of the wound in the bulbous urethra. The convalescence was satisfactory, and although it has been necessary to dilate for stricture at the site of the operation, yet the patient has regained perfect control over his sphincters.

Antigonococcic Serum.

DR. GEORGE K. SWINBURNE, New York, read this paper. Since June, 1906, he has used the serum almost without interruption on a large variety of cases. Since September, 1907, he has treated 69 cases, 41 dispensary and 28 private cases. The serum was used in 14 cases of chronic relapsing epididymitis, 10 of which were dispensary cases, and in almost all there was marked improvement. The striking relief noted was in the diminution or quick cessation of the pain. In the cases of acute epididymitis, 27 in all, the majority were relieved of pain within forty-eight hours, and almost all went on to uninterrupted recovery. There were 4 cases of muscular rheumatism in connection with chronic gonorrheal disease treated with the serum. Two were relieved and 2 received no apparent benefit. There were 10 cases in which there was muscular rheumatism with apparent involvement of one or more joints. The majority of these yielded promptly, 1 was not relieved, and 2 were but slightly improved. Five cases of pure joint lesions were treated, and responded promptly to the serum. They all followed a primary attack of gonorrhea. In 2 cases of gonorrheal kidney in which the serum was used there was no improvement. Though the serum is supposed to have no power over the gonococcus, yet in 2 cases of persistent presence of gonococci in the urethral discharge the organisms disappeared after the use of the serum. In 1 case of acute prostatitis in which the serum was used once a day for three days, there was relief of the pain and throbbing. It was used in 1 case of acute vesiculitis with immediate benefit.

DISCUSSION.

DR. LOUIS E. SCHMIDT, Chicago, has used the serum treatment in a number of cases of prostatitis and epididymitis, and has noted all kinds of complications during the course of the serum treatment with no benefit whatever.

Operative Treatment of Acute Gonorrheal Epididymitis.

DR. FRANCIS R. HAGNER, Washington, gave a further report. He published his original paper in the *Medical Record*, Oct. 13, 1906. The operative treatment of gonorrheal arthritis was the procedure that suggested operative intervention in these cases. In every case operated on fluid had been present in the tunica vaginalis, varying in amount from two drams to two ounces. This fluid resembled that seen in gonorrheal joints, in that it was usually slightly blood-stained and contained a varying amount of fibrinous material in which are entangled a few leucocytes. The parietal layer of the tunica vaginalis was congested. That portion over the epididymis was intensely so, and seemed to be the seat of small punctate hemorrhages. In a number of cases the entire epididymis was covered with a false membrane. It is the exception if this condition does not exist to some degree. The relief from pain and the rapid absorption of the inflammatory exudate seem to be just as great whether or not pus is obtained. Only the severest cases have been operated on. Since March, 1905, he had operated on but 19 cases, not more than 10 per cent. of the patients of this class. There was but one case that was not relieved absolutely of all pain on recovery from the anesthesia. There was a remarkable difference between the condition of the patients before and after operation. It is interesting to note the fall in the leucocyte count, which in one case dropped from 33,000 to 8,400 in forty-eight hours. There was a parallel fall of the temperature and pulse rate. There had been no cases of infection following the operation, recurrence, atrophy of the testicle, or other distressing sequelæ. In every case the temperature had been lower after operation than before. Pus was present in 17 of the 21 cases, being in the globus minor in 12, in the globus major and minor in 3, in the globus major in 1, and in the tunica vaginalis in 1 case. Of these 21 cases, gonococci were demonstrated five times in the pus from the epididymis, and once from the tunica vaginalis when none could be found in the epididymis. One of the most remarkable effects of this operation is the very rapid disappearance of the induration in both the cord and the epididymis. The wound is usually healed in less than a week. None of the patients have had the hard, nodular condition of the globus minor lasting for a long time, such as persists so frequently in those treated without operation. On an average, the patients are up and about and free from pain in five days. The urethral discharge does not increase afterwards.

DISCUSSION.

DR. SAMUEL ALEXANDER, New York, said he had employed this operation extensively in the service at Bellevue Hospital, and had achieved very nearly, although not quite, as good results as Dr. Hagner had reported. In five cases of acute epididymitis complicated with prostatic abscess pure cultures of the streptococcus were found.

DR. J. H. CUNNINGHAM, JR., Boston, has done the operation in six cases, and has observed the same quick relief that Dr. Hagner reports. Some induration remained, however, and in four of the cases the urethral discharge returned.

Other Cases Reported.

DR. J. BENTLEY SQUIER, New York, reported some unusual cases; DR. VAN DER POEL, a case of teratoma of the testis; and DR. HUGH CABOT, Boston, the case of a man, 50 years old, in whom varicose veins of a papilla of the kidney were a cause of persistent hematuria.

NEW HAMPSHIRE MEDICAL SOCIETY.

One Hundred and Seventeenth Annual Meeting, held at Concord, May 14-15, 1908.

The President, DR. J. H. NEAL, Portsmouth, in the Chair.

Standard Reorganization Adopted.

The House of Delegates had its first meeting the night before the opening of the sessions of the society, with a very creditable attendance. The report of the secretary contained some valuable suggestions, which were referred to a special committee; the committee subsequently recommended an approval of the election of alternate delegates by the component county societies, the publication in one volume of the earlier transactions of the society, and advised the appointment of a committee on the subject of education and the enlightenment of the public on sexual matters and venereal diseases. The last recommendation was laid on the table by the House, and the matter of organization of a branch association, referred by the Secretary of the American Medical Association, was deemed unadvisable at present.

The report of the Committee on Revision of the Constitution, appointed one year ago, read by Dr. Ira J. Prouty, Keene, the Chairman, suggested a number of amendments, the leading one being the adoption of the component county society idea. After a free interchange of opinions, the amendments as a whole were adopted, to go into effect May 1, 1909, the beginning of the next fiscal year; so that on that date, the New Hampshire Medical Society, after five years' consideration of this very important question, will place itself in complete harmony with practically all other state societies.

It was unanimously voted to send the secretary, at the expense of the society, to the meeting of the state secretaries, at Chicago, June 1, and a liberal appropriation was made for clerk hire for his office, in view of the increased work necessitated by the new order.

State Tuberculosis Sanatorium.

In 1902, the society, through a representative committee, heartily advocated legislation by the state, establishing a state sanatorium for consumptives: but, notwithstanding early and favorable action by the legislature, not even a site for its location has yet been accepted by the governor and council. A strong resolution, introduced by Dr. John W. Parsons, of Portsmouth, and unanimously adopted by the House of Delegates and the society in general session, called on the executive officers for immediate relief for these unfortunates. Drs. Smith of Hanover, Parsons of Portsmouth, Crossman of Lisbon, Morse of Newmarket, and Flanders of Dover, were appointed a committee to carry into effect the purposes of the resolution.

The reports of the treasurer and trustees showed the financial condition to be sound and substantial, there being to the credit of the society more than $4,500.

Twenty-nine new members have been elected; six have died during the year, and three have been dropped for non-payment of dues—a net gain of twenty.

The Committee on Medical Defense was continued for another year, and specific instructions were given to the Committee on Legislation, to secure a law providing for the appointment of expert medical witnesses by the court.

The next meeting will be held at Concord, May 13-14, 1909.

Officers for 1908-09.

The following officers were elected:
President—Dr. John M. Gile, Hanover.
Vice President—Dr. Frank Blaisdell, Goffstown.
Secretary—Dr. D. E. Sullivan, Concord.
Treasurer—Dr. D. M. Currier, Newport.
Delegate to A. M. A.—Dr. William T. Smith, Hanover.
Alternate—Dr. F. A. Stillings, Concord.
Councilors—Dr. A. H. Harriman, Belknap county; Dr. M. S. Woodman, Grafton county.

Relations of the Medical Profession to the Public.

The general meeting was called to order by the president at 11 o'clock, May 14.

After the appointment of committees and the introduction of visiting delegates, the president delivered the annual address. While giving due credit to the long strides taken in the treatment of disease—such diseases, for instance, as pneumonia, tuberculosis, diphtheria, etc.—he stated: "Preventive medicine is the branch of medicine which has led the profession into a field in which it has beocme a great factor in the industrial world. Through this the profession has performed a service which could not have been accomplished by any other agency. In this field we have produced results, the attainments of which have made the world pause with astonishment and awe. I heard Secretary Taft say before the Washington State Medical Association in Seattle last September," continued the speaker, "that the medical profession had made it possible for the United States to construct the Panama Canal, and that is the most gigantic proposition which has been contemplated in this, 'The Age of Progress.'"

The orator called attention to the great progress which has been made in the treatment, or, rather, the prevention of yellow fever, stating that thoroughly practical methods will now prevent the disease in any locality. Speaking of smallpox, he said that the death rate from this disease is about one-seventieth part of the death rate of pre-vaccination times, the severity of the disease also being lessened, as a consequence of the partial immunity inherited as a result of vaccination in previous generations. "There is every reason to believe," said the speaker, "that general and repeated vaccinations would stamp this disease from the face of the earth. But there will always be a few demagogues, a few disbelievers, and a few fools, and for this reason the profession will be obliged perpetually to wage war against this scourge."

Typhoid fever, tuberculosis and diphtheria were also discussed and the author urged on the profession the duty of educating the public in modern hygienic principles, at the same time commending the faithfulness and unselfishness with which physicians ever seek to prevent disease putting their most strenuous efforts into work for the good of humanity, which often reduces their own finances.

Hospital abuse, so-called, was next considered, the responsibility for which was placed squarely on the physician himself. "Does he tolerate the abuse," asked the speaker, "as a result of his philanthropic instinct, over which he has no control? Such an assumption is ridiculous. He renders his services to the rich and the poor alike for the prestige which he hopes to obtain as a result. He robs his brother of his legitimate means of livelihood and at the same time croaks at his own contemptible conduct. He not only tolerates the abuse, but he aids, abets, and assists to the fullest extent of his ability in continuing it. When the medical profession, individually, shall say to all people and to all corporations, 'We will render to all alike the best service that lies within us, whether rich or poor, demanding from all who are able a fair recompense, and from those who are not able, no recompense,' then, and not earlier, will the requiem of the hospital abuse be sung."

He further said that while the fact is well recognized that the results from medical expert testimony are far from satisfactory, and the knowledge of this condition of affairs is a source of regret and shame to every honest physician, for which he had no disposition to offer an apology, yet the responsibility rests only in part with the physician. The speaker denounced emphatically the evil which tends to exaggerate to the public eye that for which the profession is responsible—that is the method pursued by the lawyers before the courts in distorting the physician's testimony to suit the ends of their case, with the result that medical expert testimony is ridiculed by the press and the public in general.

Present Understanding of Non-tuberculous Joint Disease.

Dr. Joel E. Goldthwait, Boston, said that it must be recognized that the body is a machine, and that the adjustment of that machine depends on just as perfect balance as the adjustment and successful operation of an automobile, and no one with wisdom would think of operating an automobile if its axle or some other part were twisted or out of order; for, though a man might make the thing go, it would mean too great a strain on the tire in places, and one would know that sooner or later he would overturn the machine. In like manner, if the human machine is used in such a way that the balance of the body is disturbed, undesirable consequences result.

Remember that this subject is not worked through. Remember that rheumatism is not an entity, that many of the conditions are purely joint conditions, many are muscular conditions, but there is some way of finding out what those conditions mean, and it is up to you and me as physicians to bring intelligence and common sense and skill to bear in the treatment. A great many conditions we can relieve right off; a great many of the others we can control. Some of them we fail to control, but that is true of all classes of medicine at the present time I believe, and I believe that this class will get smaller and smaller the more we study such cases. It is for you, in general practice, who see these cases in the beginning, not to wait till the patients are in great danger and then bring them to the specialist to make them well, but get at them in the beginning before that disease has gotten hold of them to any extent, and then you can restore your patients to normal health with much satisfaction.

DISCUSSION.

Dr. S. S. Dearborn, Nashua, said that if we are not to mistake arthritis, we must be on the alert to recognize it. If we assume that rheumatism is due to infection, the connection between it and the condition of the fossæ becomes obvious.

(*To be continued.*)

AMERICAN NEUROLOGICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Philadelphia, May 20-22, 1908.

The President, Dr. Charles W. Burr, Philadelphia, in the Chair.

(Continued from page 69.)

Localized Epileptic Convulsions without Gross Lesions of the Cortex of the Brain.

Dr. **Herman H. Hoppe**, Cincinnati, confined his remarks to cases showing genuine epileptic convulsions and not those of the Jacksonian or reflex type. Only cases in which the physical examination was negative were selected. In one class of cases there develops, without previous epilepsy, a status hemiepilepticus which results fatally in a short time. In these cases operation is futile. It is often difficult, even after prolonged observation, to decide whether a given case of localized epileptic seizure is due to an organic lesion or not, as there are so many forms of trauma and disease which may cause an organic lesion. We must conclude, however, that these are cases which are not produced by organic lesion. When the loss of consciousness occurs first and the convulsions follow and are limited to a small group of muscles they are undoubtedly epileptic and not Jacksonian. There is a second class of cases in which attacks recur for years and in which there is no progression. The attacks always occur in the same way. In Jacksonian epilepsy there is steady progression. Differentiation must also be made from hysterical epilepsy.

DISCUSSION.

Dr. **L. Pierce Clark**, New York, stated that in a series of 11 cases of status hemiepilepticus at the Craig Colony there was only one death. It is not uncommon for patients of this type to go through attacks 15 times or more. He thinks that the cases mentioned by Dr. Hoppe are not without suspicion of organic lesion. He believes that the underlying lesion in focal epilepsy is a chronic meningoencephalitis.

Dr. **E. E. Southard**, Boston, thinks that the possibility of bacterial etiology should be looked into in these cases.

Dr. **W. G. Spiller**, Philadelphia, thinks that in cases of doubt as to the presence of an organic lesion, operation should be done early, even if it turns out to be only exploratory, for in case of tumor, success can be assured only by early operation.

Dr. **B. Sachs**, New York, stated that many cases of epilepsy are due to lesions sustained early in life. That there is some change either microscopic or macroscopic we must maintain until there is strong evidence to the contrary. In a case in which focal epilepsy comes on suddenly in an individual who has never had epilepsy before, the idea of operation might well be entertained.

Dr. **J. J. Putnam**, Boston, said that in these cases, while there is no local lesion, there is an area of maximum irritability.

Dr. **F. X. Dercum**, Philadelphia, stated that in a disease so hopeless as epilepsy, operation should be done if there is only a shadow of a chance of its doing good.

Dr. **C. K. Mills**, Philadelphia, said that the more the question of operation is studied, the greater the success. A species of Jacksonian epilepsy sometimes occurs inside the general epileptic attack, and when this is the case, operation is indicated.

Dr. **Hoppe** agreed that microscopic changes could perhaps be found in all cases of so-called idiopathic epilepsy. He believes in operation in the cases Dr. Spiller spoke of, but his cases were not of that kind.

Sane Prototypes of Insane Mental Processes.

Dr. **Theodore H. Kellogg**, New York, said that insanity is never a spontaneous mental variation, but is always evolved on persistent lines of mental action. All insane mental processes have their correlative sane prototypes which have not been adequately studied. He compared the insane mental processes with their sane prototypes in the following order: Delusions of the sane as the casual prototypes of the false beliefs of the insane; extremes of conduct of the insane as uniformly modeled after sane exemplars; insane emotions, propensities, and impulses as directly derived from their sane prototypes; the hallucinations and illusions of the insane as mere projections of the prototypic sensorial disorders of sanity.

DISCUSSION.

Dr. **H. R. Stedman**, Boston, said that the only mental conditions it seems hard to trace are the perversions of instinct, such as sexual perversions, and the eating and drinking of loathsome things.

The Course of Sensory Impulses in the Spinal Cord.

Dr. **Carl D. Camp**, Ann Arbor, Mich., said that other sensations than pain and temperature, as first taught by van Gehuchten, are conveyed in the spinal cord by fibers which take their course in different parts of the cord. Pain sensation enters the posterior horn by the posterior roots and ascends in the gray matter for variable distances varying from 2 to 8 segments, crosses in the posterior commissure, and ascends in Gowers' tract to the cerebrum either directly or indirectly. Heat and cold enter by the posterior roots and follow the same course as pain, but by distinct and separate fibers. Tactile sensation enters by the posterior roots and passes up in the posterior columns on the same side without decussation. The sense of position comes from the joints; of motion from the muscles. These enter by the posterior horn, run to the cells in Clark's column, possibly ascend in the gray matter of the same side for a number of segments, and then pass up in the direct cerebellar tract of the same side.

Diagnosis of Epilepsy and Dementia Præcox.

Dr. **L. Pierce Clark**, New York, presented the results of a joint study with Dr. E. W. Scripture on the epileptic voice in which they had found a characteristic and constant loss of melody. The epileptic speech is "plateau" in form. No other nervous or mental disorder shows the epileptic voice type. The voice sign is dependent on the chronic exhaustion or degeneration of those cortical elements which constitute the brain pathology of epilepsy proper. In three-fourths of all cases of epilepsy one may detect the voice sign without any other knowledge of the disorder being present. Dr. Clark also showed four colored drawings of the fundus changes found by Dr. Tyson and himself in all cases of dementia præcox. He laid stress on the point that one must not consider all the signs and symptoms of the eye syndrome to depend on the syndrome in prognosis and diagnosis of this psychosis.

The Symptom-Complex of Occlusion of the Posterior-Inferior Cerebellar Artery.

Dr. **William G. Spiller**, Philadelphia, enumerated in detail the symptoms of this lesion.

Thrombosis of the Posterior Inferior Cerebellar Artery with Autopsy Revealing the Lesion in the Medulla.

Dr. **Henry M. Thomas**, Baltimore, referred to several cases reported in 1896. The second patient died two and a half years after onset of symptoms; autopsy was refused. In a third case, a man of 59, who, a week before entering the hospital had intense giddiness, pain in left side of face, difficulty in talking and swallowing, drooping of left eye, and weakness of left face, the examination showed an extremely ill man, with marked vascular, cardiac and renal involvement. Sensorium dull. Constant hiccough. Left pupil smaller than right. Slight left ptosis. Slight divergent squint of left eye. Dissociated sensory disturbance on left face, right arm, and leg. No sweating of left side of face. Death in four days. Autopsy, among much else, revealed thrombosis of left posterior inferior cerebellar artery.

Discussion on Papers of Spiller and Thomas.

Dr. **B. Sachs**, New York, said that he had a case of unquestionable thrombosis of the inferior cerebellar artery a short time ago; the patient has practically recovered.

Dr. T. Diller, Pittsburg, said that he had seen three or four such cases.

Dr. Charles E. Beevor, London, Eng., said that he had not come across any case similar to those described.

Dr. D. J. McCarthy said that it should be borne in mind that there is a wide variation in the posterior branches given off by the circle of Willis, hence the symptoms may differ greatly depending on which vessels are involved.

Dr. Spiller said that the symptom group he described is so striking that if it is kept in mind a diagnosis could be made without difficulty.

Dr. Thomas agreed with Dr. Spiller and said that about 30 cases could be collected, both with and without autopsy, showing this sharp cut symptomatology.

A Case of Myasthenia Gravis with Negative Pathologic Findings.

Dr. J. Arthur Booth, New York, reported the case of a lad of eleven years who presented the familiar symptom-complex of the disease with a rather acute invasion, following an operation for adenoids. Death occurred from failure of respiratory musculature. Examination of the central nervous system was negative and specimens taken from muscles and nerves did not show anything abnormal. Thyroid, parathyroids, and pituitary glands were normal; there was slight simple hypertrophy of thymus gland

DISCUSSION.

Dr. N. E. Brill, New York, regards the enlargement of the thymus in this case as distinctly pathologic. Abnormalities of the thymus occur in 20 per cent. of the cases of myasthenia gravis.

Dr. W. G. Spiller, Philadelphia, recently had a patient found to be eliminating an excess of calcium chlorid in the urine. He was put on calcium chlorid, with distinct improvement.

Dr. Booth does not agree with Dr. Brill that the thymus in his case was pathologic.

Rest Treatment in Relation to Psychotherapy.

Dr. S. Weir Mitchell, Philadelphia, read this paper which appeared in full in The Journal, June 20, page 2033.

DISCUSSION.

Dr. F. X. Dercum, Philadelphia, said that the rest treatment was certainly original with Dr. Mitchell and that the only remarkable fact about the method is that it makes use of simple physiologic means. The danger in the newer methods of so-called psychotherapy is that they will be used to the neglect of physiologic means.

Dr. J. J. Putnam, Boston, said that no small factor in Dr. Mitchell's success is his glorious courage and inspiring personality. He agreed with Dr. Mitchell that neurasthenia is often purely physical in nature.

Dr. Charles L. Dana, New York, said that Dr. Mitchell's colleagues have never questioned the value of this original contribution to therapeutics. In reference to psychotherapy it is true that many people are going to the wrong place for treatment and that physicians should acquire a knowledge of all that is good in the way of treatment by whatever name it is called and be prepared to use it.

Dr. B. Sachs, New York, thinks that the association should stand in opposition to the psychotherapy idea as recently developed, because it has been horribly overdone, but that physicians should go along as they have always done exerting their influence often perhaps unconsciously, but nevertheless with good effect. He does not think it necessary to coin any new terms.

Dr. Charles E. Beevor, London, stated that in England the Weir Mitchell treatment is used with the greatest success; also that psychotherapy has not, up to the present time, invaded England.

Dr. Philip Coombs Knapp, Boston, endorsed absolutely everything that Dr. Mitchell said. The physical condition of the patient is too often overlooked. The most important thing is to put the patient on the best possible physical basis.

Data Regarding Paresis and Brain Disease in Railway Employés.

Dr. Philip Coombs Knapp, Boston, as chairman of a committee appointed to collect data as to the existence of general paresis and general brain diseases in railway employés, reported that the committee had gone far enough to learn that those diseases are sufficiently prevalent to constitute a grave danger to the traveling public and that it would be desirable to have locomotive engineers and train dispatchers examined regularly by competent neurologists.

The Types of Encephalitis.

Dr. E. E. Southard, Boston, considered only the exudative forms of encephalitis which fall into three groups: (1) Acute, including coccal and typhoid forms; (2) subacute, including tuberculous and luetic forms; (3) the progressive form, or dementia paralytica.

Occupation Neuritis of the Deep Palmar Branch of the Ulnar Nerve.

Dr. J. Ramsey Hunt, New York, described this well-defined clinical type of occupation atrophy of the hand with the following clinical characteristics: (a) Atrophic paralysis of the intrinsic muscles of the hand, supplied by the deep palmar branch of the ulnar nerve; (b) reactions of degeneration in the intrinsic muscles of the hand, supplied by the deep palmar branch of the ulnar nerve; (c) no objective sensory disturbances of the hand or fingers. They are to be regarded as due to compression neuritis of the deep palmar branch of the ulnar nerve as it passes between the muscles of the hypothenar region on its way to the deeper structures in the palm.

DISCUSSION.

Dr. F. W. Langdon, Cincinnati, thinks that there is a tendency erroneously to ascribe this condition to progressive muscular atrophy.

Dr. Philip Coombs Knapp, Boston, said that Dr. Hunt's careful work and his explanation are very convincing, and that these cases have been described as beginning spinal myelopathy.

Confusional Insanity and Dementia Præcox.

Dr. Philip Coombs Knapp, Boston, stated that too sharp a distinction has been drawn between confusional insanity and dementia præcox, so-called, in the endeavor to establish two distinct diseases. The confusion of the former and the stupor of the latter are only two stages of what is really the same disease. One is a disturbance of projection, and the other of perception. The pathogenesis of these conditions has not yet received sufficient study. Intoxication and exhaustion play an important rôle. The so-called dementia præcox is not always precocious, as it may begin after fifty, neither does dementia always occur. Dementia præcox, as a term characterizes the disease too strongly as hopeless, for it is not ordinarily progressive, and is sometimes curable.

Facial Paralysis.

Dr. G. A. Watermann, Boston based his paper on a number of cases of peripheral facial palsy. There was very slight difference in the side or sex affected or in the season of the year. However, exposure to cold and drafts played an undoubted causative rôle; as did also the toxins of syphilis, nephritis and the like. Ear disease also played a part. The character of pain at the beginning was of no prognostic import.

Prognosis of Spinal-Cord Tumors with Operation.

Dr. William C. Krauss, Buffalo, N. Y., said that the first operative case of spinal-cord tumor was that of Gowers and Horsley in 1888. There was one series of 50 cases in the first 10 years; a second series of 50 in the next 5 years, and a third series of 50 cases in the next 5 years. The prognosis has gradually grown better and better, and is especially good in cysts and sarcoma.

Delayed Apoplexy (Spätapoplexie) with Report of a Case.

Dr. A. R. Allen, Philadelphia, concluded that traumatic delayed apoplexy is an entity; that it may be due to an occlusion of the arteries; that when hemorrhage occurs it is not due to necrosis outside of the artery, and that the arterial changes are the result of the trauma.

Medicolegal

Check Interposed to Use of Property for Tuberculosis Sanitarium.

The Supreme Court of North Carolina had, in the case of Cherry vs. Williams, an action to enjoin the erection and use of buildings on a cerain lot, in the city of Greensboro, for a sanitarium for the treatment of tuberculosis, etc. The defendant, admitting his purpose to construct and use buildings for the treatment of consumptives, and at the place indicated, offered a large amount of evidence, including affidavits of specialists, eminent in their profession, and in the treatment of tuberculosis in hospitals and otherwise, to the effect that "a sanitarium for the treatment of consumptive patients, located in the city of Greensboro, properly maintained and conducted, would not be a menace to the health of the community in which it is situated, nor to the public health; that such sanitariums are conducted in large and populous cities all over the country where the climate is suitable for the patients, and that experience has shown that such sanitariums are not a menace to the public health, but rather a benefit;" that the proposed locality was not thickly populated, and consumption is not contagious, nor an infectious disease; and that the defendant was qualified to conduct the proposed sanitarium properly and intelligently. But the court thinks that the conditions suggested, if established, would come well within the definition of an actionable nuisance, and, if there was a well-grounded apprehension that neighbors would be unreasonably exposed to serious danger from a disease of the nature of consumption, the temporary injunction should be continued to the final hearing. The injury threatened in such case would be irreparable. It says that the authorities in that state will uphold the position that, when there are facts in evidence which give good reason to believe that the owner of property in the residential portion of a thickly settled vicinity is about to devote it permanently to a use which imports serious menace to the health of the owners and occupants of adjacent property, such use should be restrained until the facts on which the rights of the parties depend can be properly determined at the final hearing of the case.

In this case there was evidence on the part of the plaintiff, direct and specific, that the erection and use of a hospital in that particular locality, in the manner and for the purpose proposed, would be a source of real danger to the lives and health of numbers of people living in that vicinity, and while the affidavit of the defendant himself made specific response, a large portion of the supporting evidence offered by the defendant was very general in its terms, and made without reference either to the special locality or to the special manner in which the particular hospital was to be constructed and carried on.

If the defendant desired to proceed with the construction of his buildings and risk the results of the trial, the restraining order might be modified to that extent, but any and all use of the buildings for the purposes indicated should be restrained to the hearing.

A Physician Suing for Services is Subject to Cross-Examination.

The Supreme Court of Colorado says, on the appeal of Purse vs. Purcell, that the latter-named party, a licensed physician, brought this action to recover the reasonable value of professional services, which, at the defendant's request, he rendered to the defendant's children who were sick of scarlet fever.

The answer denied that the services were of any value whatever, and alleged that the plaintiff prescribed for and attended five of the defendant's children, two of whom the defendant admitted, had scarlet fever and diphtheria, and said the others had diphtheria, but not scarlet fever—though the plaintiff treated all of them only for the latter—and that, by reason of the defendant's negligence, or want of skill, in making the proper diagnosis and prescribing the appropriate treatment, three of the children died. Substantially the same matters, alleged as a defense, were set up in two separate cross-complaints or counterclaims, in each of which the defendant asked judgment against the plaintiff in the sum of $5.000 for malpractice.

The court is clearly of opinion that a case of malpractice was not made out by the evidence. Indeed, the defendant did not in his brief press his claim in that behalf, apparently because his own expert evidence precluded a judgment in his favor. It also says that, in the absence of any evidence of value to the contrary, or of evidence inconsistent with the plaintiff's testimony as to the extent or character of the services, it might be that the jury ought to find in the plaintiff's favor for the amount claimed. But it thinks that prejudicial error was committed in limiting the scope of the cross-examination of the plaintiff by the defendant's counsel, for had the questions on cross-examination been allowed, and the plaintiff required to answer, the jury might have found, on substantial evidence, that the services were of less value, or not so extensive as the plaintiff said they were.

The plaintiff, the court says, testified in his own behalf merely to the effect that he was a licensed physician and had, at the defendant's request, attended the latter's children, and that the bill for which he sued was the customary and reasonable fee, no part of which had been paid. In his complaint he alleged that the children were sick with scarlet fever, and that the services rendered were on that account. On cross-examination he was asked, among other things, by the defendant's counsesl, what was the matter with the children, what medicine he gave them, and was asked to describe to the jury their symptoms, and all the indications of disease which they exhibited. As throwing light on the extent and value of the services, as well as bearing on the diagnosis and method of treatment, it was competent under the issues to ask such questions.

The questions propounded were germane to the first defense of the answer, which denied that the services which the plaintiff rendered were of any value to the defendant. It was necessary for the plaintiff to prove that his services were of value, and when he himself testified as to that issue, the defendant might properly, by cross-examination, ask what the services were, and what the plaintiff did, and as to the symptoms and nature of the malady from which the children were suffering.

But if the questions propounded by the defendant had been answered by the plaintiff, it might be that there would have been evidence before the jury from which they might have concluded that the plaintiff's services were not so valuable as he claimed them to be.

1 *Surgical Shock. G. Crile, Cleveland, Ohio.
2 Achondroplasia. W. N. Bullard and A. W. George, Boston.
3 Alpha-monobrom-Isolvalerylurea. A New Nerve Sedative and Somnifacient. W. H. Porter, New York.
4 *Local Treatment of Acute Inflammations of the Throat from the Standpoint of Pathology. J. L. Goodale, Boston.

1. **Surgical Shock.**—Crile omits theoretic discussion and deals with certain phases of shock in their relation to surgical practice. Repeated and accurate observations on the blood picture may differentiate between hemorrhage and shock. He discusses certain preventable factors, dwelling particularly on the psychical element which does not receive adequate attention, and warns against overanesthesia.

4. **Inflammations of the Throat.**—Goodale thinks that in a beginning tonsillitis antiseptic applications may perhaps be used with benefit and their effect, if any, will be to abort the local infection. If the disease is not checked at the outset by the sterilization of the parts, but proceeds to the formation of white spots in the crypts with systemic involvement, further application of antiseptics may be not only useless but

harmful. It would appear possible that antiseptics may retard convalescence in two ways: *First*, by *diminishing* the number of bacteria in the crypts, which are generating toxin, and consequently prolonging the period required for the formation of the requisite amount of antibodies; second, by their destructive action on the tissue cells and phagocytic leucocytes of the host. Forcible application of antiseptics may be followed by increased fever and cervical adenitis, indicating heightened absorption of toxin into the system. This phenomenon may be compared to the depression which follows the infection of too large a dose of vaccine in patients undergoing opsonic treatment. In certain cases in which acute tonsillitis appears to be aborted by local antiseptics, inflammatory manifestations may follow after a day or two in the neighboring regions and last for a number of days or several weeks. Here, the possibility is suggested that the checking of the tonsillitis checked also the establishment of immunity, and that for its final accomplishment a longer period of growth of the organism on the membranes of the nose, larynx, trachea or bronchi was necessary. In this connection may be recalled the protracted duration of nasal diphtheria, as compared with the relatively brief time occupied by the pharyngeal disease.

5 *Method of the Spread of Yellow Fever. W. C. Gorgas, Ancon, Canal Zone.
6 *Influenza: Its Diagnosis from a Morphologic Standpoint in Stained Specimens of Sputum. G. W. Stiles, Washington, D. C.
7 Liver Symptoms in Cardiac Disease. L. F. Bishop, New York.
8 Adverse Suggestion. A. F. Riggs, New York.
9 Relation of Pleurisy to Pulmonary Tuberculosis. H. S. Goodall, Lake Kushaqua, N. Y.

5. **Yellow Fever.**—Gorgas describes the methods used in suppressing yellow fever in Havana and in the Canal Zone. He shows how the reduction in numbers of the stegomyia, even though short of extinction, can eliminate the disease. With a hundred stegomyiæ to the square yard the introduction of a yellow-fever patient means the probable infection of many mosquitoes which will convey the disease to non-immunes present in the community, and each fresh case is likely to infect more mosquitoes and through them more non-immunes. As the number of mosquitoes is gradually reduced to 50, 25 and 15 to the square yard, the chances of an epidemic become smaller and the epidemic itself milder. By the time the mosquitoes are reduced to 10 per cent. of the original number, even if a yellow-fever patient is introduced, the chances of his being bitten, and thus infecting a mosquito, are minimized; and while it is possible with ten mosquitoes to the square yard for one mosquito to become infected and give yellow fever to some other non-immune in the same house, it is not probable that this second yellow-fever case will infect a second stegomyia. A certain number of mosquitoes are necessary for the propagation of yellow fever, but this number is ordinarily largely exceeded in yellow-fever countries. While it is probably impossible under any sanitary organization to exterminate the stegomyiæ altogether, it is possible to reduce them below the yellow-fever point, but so long as the number remains above this point we shall continue to have yellow fever when non-immunes are present, no matter how much we fumigate or how carefully we isolate the sick. Gorgas regards this as a reasonable explanation of the disappearance of yellow fever, before we knew of its propagation by mosquitoes, from Philadelphia, New York, Boston and Quebec, cities in which the stegomyia is not normally found, but used to be carried there on the sailing vessels.

6. **Influenza.**—Stiles reports a hundred tabulated cases of suspected influenza, in which examination of the sputum was undertaken with a view to determining the trustworthiness of a method of diagnosis based on the morphologic characters alone of the organism found in the sputum. Several slides were made from each specimen, and, after drying in air and gently fixing by heat, were stained with alkaline methylene blue and dilute solution of carbolfuchsin (about one part to eight or ten of water). He describes the characters of the *Bacterium influenzæ*, and concludes as follows: 1. In view of the results obtained from this series of cases, I can not too strongly emphasize the necessity of making a routine microscopic examination of sputum from cases manifesting general respiratory symptoms of disease. No matter what the previous diagnosis may have been from the symptomatology alone, further light on the condition of the patient may be obtained from a microscopic study of the sputum. 2. Valuable information may be obtained from a brief study of well-stained specimens of sputum from suspected or complicated cases of influenza. 3. A few cases resembling tuberculosis may be due to infection of influenza bacilli alone or to a mixed infection of the two organisms.

10. Abstracted in THE JOURNAL, May 30, 1908, p. 1818.

11. **Opsonic Therapy.**—Illman and Duncan summarize their results with opsonic treatment in 30 cases, of which 13 were tuberculous, 5 gonorrheal, 6 staphylococcic, 3 streptococcic, 1 mixed, 1 colon, and 1 typhoid. Their conclusions are practically as follows: Vaccine therapy offers a chance of cure in many cases of disease heretofore regarded as incurable. In the large majority of cases stock vaccines are just as efficient as autogenous vaccines. Patients can be treated with fewer actual index observations than was at first supposed. Patients treated with clinical phenomena alone as a guide should only be so treated by some one well versed in vaccine therapy, and then only after having been under previous observation for a period long enough to have determined "the phase" the patient is in. Very small initial doses should be employed when the opsonic index has not been previously determined. The best results at the present time are obtained in tuberculous conditions and staphylococcic or streptococcic infections, as in acne. To get the best results vaccine treatment must be instituted as soon as the diagnosis is made. They report the thirty cases in detail.

12. **Tuberculin Inunction.**—Moro recommends as a substitute in many cases for the ocular and subcutaneous tuberculin reactions the following method: Koch's old tuberculin, 5 c.c.; anhydrous wool fat, 5 gms. A piece the size of a pea is rubbed into the skin of the chest or abdomen for about half a minute over an area of four square inches. On the following day, or later, the appearance of small papules which last for about a week indicates a positive reaction. Moro asserts that a positive result by this method is as conclusive as those of Calmett's or v. Pirquet's methods. The method is said to be entirely harmless.

15. **Mercury in Tuberculosis.**—Bernart, as the result of observation in the treatment of 422 syphilitics, of whom many were tuberculous, by intravenous injections of mercury, arrives at the following conclusions:

1. The control of the active syphilis in many of the tuberculous patients seemed for the time to benefit the tuberculosis also.
2. In patients with pulmonary tuberculosis, after the first control of the syphilis and if the treatment was continuously pushed, a few months would show a gradual aggravation of the tuberculosis.
3. The genitourinary tuberculous patients, outside of the benefit to their syphilis, showed no improvement in their tuberculosis.
4. Two patients with tuberculous eye trouble were benefited, one markedly so and the other but moderately so. This is not surprising, as the intravenous injections of mercuric chlorid exert a decided and beneficial influence over infections and ulcerations of the eye.
5. The patients with pulmonary tuberculosis, evidently suffering from the absorption of septic materials, probably due to a second

any germ infection, were decidedly benefited up to a certain point, after which, if the mercurial treatment was continued, their retrogression was rapid

19. **Retrograde Catheterization in Stricture.**—Jonas considers that there has been an unjustifiable lack of progress in treating benign urethral strictures, which he attributes in part to the want of surgical training in the older genitourinary physicians and to the public dread of operations on the penis. Treatment of strictures with sounds should be reserved for strictures of moderate size, frequently called of large caliber. For strictures of small caliber, and those admitting only a filiform bougie, urethrotomy is better, preferably external urethrotomy (except in strictures of the pendulous urethra, when internal urethrotomy may be chosen) Jonas favors urethrotomy in all cases in which the urethra can not easily be kept open by bougies, or in patients with pain or annoying symptoms, even when it is possible to pass a sound of normal size. All scar tissue should be completely excised When in external urethrotomy it is impossible to pass a filiform bougie, an attempt may first be made to find the proximal opening of the urethra from the perineal incision but failing speedy success, the bladder should be opened above the pubis and a sound should be passed through the bladder to the perineum (retrograde catheterization). The sound point acts as a guide to slit open the urethra The wound of the bladder and the abdominal incision are closed at once, the prevesical tissue being safeguarded by a small cigarette or tubular drain.

36 Simplified Technic for Supravaginal Hysterectomy W Bartlett, St Louis
37 *Improved Hodgen Splint for Fractures of the Thigh G S Brown, Birmingham Ala
38 Simple Hysterectomy in Simple Cases A H Ferguson, Chicago

27. **Cancer of Sigmoid**—Moynihan endeavors to show that the descending colon and the upper part of the sigmoid flexure retain their vitality after the sacrifice of the inferior mesenteric artery and that the mobilization of the colon and the splenic flexure permits considerable displacement of these portions of the bowel, and argues that in all cases of carcinoma of the sigmoid or of the rectum, whether high or low (the proctodeum excepted), an abdominal operation seems advisable, for by this route only can the whole lymphatic territory be extirpated He describes the procedure necessary in a case of growth about the middle of the sigmoid

29 **Chorioepithelioma of Placenta.**—Davis reports a case and discusses the literature of the subject He urges the importance of examining the placenta in all cases in which pregnancy is interrupted after the fourth month Ballantyne's statement that the placenta is the key to fetal pathology should be kept in mind in all cases in which the fetus is still-born or the pregnancy is interrupted after the placenta is formed If chorioepithelioma is found, *attention must be directed to the mother.* All cases of pregnancy complicated by anomalous hemorrhage should arouse the suspicion of chorioepithelioma malignum He asks: "Shall the operator who detects chorioepithelioma of the placenta proceed immediately to hysterectomy as soon as the patient's condition justifies it, or shall he content himself with a thorough examination of the patient under ether, including curetting, and the microscopic examination of the scrapings? If these procedures give no evidence of chorioepithelioma, is he justified in allowing the patient to pass from his observation without hysterectomy?"

31 **Ureteral Calculi.**—Gibbon reports six cases, and discusses the pathology, symptoms, diagnosis and treatment, considering the operative treatment as it is applicable to stones situated in the upper third, the lower two thirds, and the vesical portion of the ureter respectively. He discusses various routes and operations, and urges the advantage in doubtful and difficult cases of the combined intraperitoneal and extraperitoneal operation

32. Abstracted in The Journal, March 14, 1908, p 911.

34. **Removal of Child from Breast.**—Reed reviews observations of the effect on the child of drugs administered to the mother It seems probable that alcohol, opium, chloroform, ether, thyroid extract and lead should be used with extreme care in a nursing woman until their status is determined; that zinc apparently has no effect, while all the other drugs investigated, atropin, arsenic, antipyrin, acetic acid, bismuth, potassium bromid, balsam of copaiba, castor oil, copper, chloral, iodin and its compounds mercury, phenacetin, quinin, salicylic acid and senna—pass over in small quantities in the milk, but rarely to a degree injurious to a sensitive babe The child, therefore need practically never be removed from the breast on account of their administration Nephritis, serious and obstinate erosion and fissure of the nipple, Paget's disease, scirrhus, sarcoma or abscess of the breast, together with local or systemic tuberculosis syphilis, erysipelas, acute articular rheumatism, acute pulmonary or pleuritic affections, and all infections and contagious diseases, osteomalacia, and all puerperal infections that are not mild and transitory in character demand the absolute separation of mother and child.

37. Abstracted in The Journal, Jan. 25, 1908, p 310.

40 **Acute Poliomyelitis.**—Holt and Bartlett present as complete a collection as possible of the epidemics of this disease so far reported, 35 in all, excluding the New York (1907) epidemic, which is to be made the subject of a special report by the medical societies They discuss the data on *communicability*, and conclude that this is unquestionably *an infectious disease*, but whether it is communicable is open to question. They believe that it is communicable but only to a slight degree. They give a tabulation of the principal facts regarding the thirty five epidemics, together with references to the literature.

41. Abstracted in The Journal, Jan. 25, 1908, p. 311.

42 **Gallop Rhythm.**—Robinson summarizes his paper as follows: Gallop rhythm of the heart is a fairly frequent clinical phenomenon, which consists in the presence of a group of three cardiac tones, none of which are murmurs It occurs under variable clinical conditions That form of gallop rhythm which is best heard at the apex, or over the central part of the precordium, may be divided into the presystolic protodiastolic and mesodiastolic types, depending on whether the extra tone falls at the end at the beginning or in the middle of each diastole Each form is associated with a characteristic cardiogram There are a number of factors which probably combine in various ways to produce the various forms of gallop rhythm Presystolic gallop rhythm is heard in two classes of cases It is heard in strongly acting hearts in which a muscle sound produced by a strongly acting, hypertrophied auricle is probably the cause of the extra tone; and in weak, rapidly acting hearts at the height of acute febrile diseases, at which time there is possibly a delay in the conduction of the heart beat from the auricles to the ventricles Under these circumstances the sound produced during the contraction of the auricles becomes distinguishable from that produced during the contraction of the ventricles In both classes of cases the extra tone seems to be produced in the auricle rather than in the ventricle Protodiastolic and mesodiastolic gallop rhythm are caused by the production of an extra tone in the ventricles The factors that probably combine to produce this extra tone are an increase in the amount and velocity of the flow of blood from the auricles into the empty ventricles and a loss of tone of the heart muscles of the ventricles The longer silent period in cases of gallop rhythm does not usually occur during diastole, but is generally a systolic silence

44 Abstracted in The Journal, Jan 18, 1908, p 233

46 **Pelvic Contraction.**—Fry emphasizes the importance of early surgical intervention before the woman has gone through the exhaustion of prolonged labor pains, and particularly before employing forceps and manipulations that may produce infection It is incumbent on the general practitioner to learn to recognize early the cases of disproportion between the infant's head and the maternal pelvis Pelvic deformity is much more frequent than is generally supposed He describes the varieties of deformity and says that pelvimetry should be performed at the eighth month of pregnancy in all primiparæ, and in those multiparæ who have passed through difficult labors He discusses in detail the three lines of treatment open in minor degrees of pelvic contraction discovered in the thirty second week: (1) The induction of premature labor; (2) elective Cesarean section; (3) delay until labor has demonstrated the resources of Nature; then (a) spontaneous delivery. (b) version; (c) axis traction forceps; (d) Cesarean section, (e) symphyseotomy or pubiotomy; (f) craniotomy.

47. **Rodent Ulcer.**—McConnell discusses the literature of rodent ulcer and analyzes 16 cases from the St Louis Skin and Cancer Hospital. Both gross and microscopic appearances were practically alike in all cases Contrary to Bland-Sutton's statement that rodent ulcer never cicatrizes, in one of these cases it had done so to a remarkable extent McConnell describes the histologic findings minutely and emphasizes the characteristic formation of the cell nests, the marked fragmentation of elastic tissue, and the fact that in one case which came to autopsy, no infiltrated nodes were found nor were there any metastases to distant structures; from which he argues the probability of permanent cure by early excision. A number of patients were treated by *x* rays for varying periods without permanent benefit The lesion and symptoms would seem to improve the patient would stop coming, and would return later when the lesion had broken down Excision followed by *x* ray treatment gave the best results

52 A Clinical Study of the Alkalinity of the Blood S Strouse, Baltimore
53 *Cardiohepatic Angle. W. J. Calvert, Columbia, Mo

53. **The Cardiohepatic Angle.**—Calvert says that clinically the value of the cardiohepatic angle in pericarditis is not decreased in the early stages of the development of dilatation of the left auricle, because the signs of the mitral lesion would be present. In enlarged hearts the lesion must be determined before an increased cardiohepatic angle is differential for an associated pericardial effusion In extreme dilatation of the heart, when differentiation from pericarditis is the most difficult, the cardiohepatic angle is of little value, unless the history of the case is known: even then it is, at best, uncertain. When pericardial effusion can be positively excluded, an increase in the cardiohepatic angle becomes a sign of mitral stenosis, because this lesion most frequently causes extensive dilatation of the left auricle and displacement of the root of the lung. When the history of the case is known, allowing heart lesions to be excluded, an increase in the cardiohepatic angle retains the value in pericarditis with effusion given to it by Ebstein and others.

56 Reaction of Anaphylaxis L S Mace, San Francisco
57 Development of the County Medical Society W T Barry, Santa Barbara.
58 A Nerve Sedative. C. Renz, San Francisco.

55 **Fallaciousness of Diagnostic Signs.**—Cooper considers that the McBurney point has been given a pathognomonic significance which it does not merit, and has caused many innocent appendices to be operated on The continuous presence of occult blood in the stools can not be relied on to indicate alimentary carcinoma Chronic apical catarrh may indicate influenza and not tuberculosis. Acid-fast bacilli may be found in non tuberculous ailments Lung tissue in the sputum does not necessarily indicate an intrapulmonic purulent collection. A diastolic puff over the aortic and pulmonary valves is sometimes due to mechanical diastolic movement of air in the neighboring lung tissue. Both leucocytosis and fever may be absent in malignant endocarditis. Cooper doubts the diagnostic value of pulsus alternans as to loss of contractibility of cardiac muscle, etc. He suggests that: 1. The time has come to state and to teach that there are no pathognomonic signs of the individual diseases, that the presence of such signs forms only one link in the diagnostic chain, and in no way excuses neglect of thorough and, if necessary, repeated investigations of our patients. 2. The use of pathognomonic terms such as gallstones crepitus and ureteral clots would better be discarded.

65 Optic Neuritis Due to Chronic Empyema of the Frontal and Anterior Ethmoidal Sinuses W. R Murray, Minneapolis

59 **Extrauterine Pregnancy.**—Barton describes a peculiar case in which, besides the left ruptured tubal pregnancy for which operation was done, there was a distention of the right tube with serous fluid and blood, which did not have the characteristics of a hydrosalpinx. He suggests the possibility of there having been a pregnancy in both tubes. He discusses the diagnosis of extrauterine pregnancy and regards irregularity in the menstrual flow as the most constant symptom. He agrees with those who think that with proper judg-

ment more lives would be saved if we were to wait a few hours until shock is over before operating. He believes that the shock is not entirely due to the hemorrhage, but that the sudden pain and the fear of dissolution are factors in it also.

67. This article was published in the *Interstate Medical Journal*, May, 1908.

69. **Surgical Operations on Diabetics.**—Riesmeyer points out that even in cases in which the general constitution of the patient seems to guarantee a good result coma and death have followed operation, while in relatively far advanced cases good results of operative intervention and improvement in diabetic symptoms have followed. It is wise to prefer palliative measures in small ailments, such as ingrown toenail, and even corns. That a good result will ensue can not be foretold with exactness, so that prognosis must be cautious General anesthesia, especially chloroform, increases the danger of coma. On the whole, the prognostic significance of operation on diabetic patients may be somewhat modified by sustaining the nutrition, the strength and the resisting power of the body by preventing or counteracting acidemia, and by reducing infection and the duration of operative procedures to a minimum.

104. **Laboratory Methods.**—Wood deals with blood examinations in their relation to the malarial parasite, leucocytosis, *Filaria nocturna*, the *Spirochata pallida*, agglutination tests, the opsonic index, etc., and also the examination of the stools in cases of severe anemia, for the eggs of bothriocephalus. The irrigation method, washing out the lower intestine once or twice daily with high irrigation of physiologic salt solution in pernicious anemia is recommended. He cautions against paying too great attention to the leucocyte count to the exclusion of physical examination, and discusses the differentiation of pneumonia and typhoid by blood examination. Leucocytosis is also an aid in prognosis, *e. g.*, in appendicitis. The Widal test has proved one of the most useful of laboratory diagnostic methods. Wright's vaccine treatment, owing to the complexity of its methods, will probably be left to special laboratories. The topical tuberculin test for tuberculosis—by the skin and the eye—is discussed, and the author considers that the latter would prove valuable if a purified and standardized tuberculin could be obtained. The article, being didactic, hardly lends itself to abstraction.

110 Treatment of Enlargement of the Prostate W. Karo, Berlin
111 Medicinal Treatment of Pulmonary Tuberculosis G L Haefele, Cleveland
112 Bier's Method in Treatment of Some Neuroses A. Gordon, Philadelphia

109 **Psychotherapy.**—Dercum says that we should always bear in mind that symptoms have a physical basis, and this is

especially true of functional nervous disease. Exhaustion plays a fundamental rôle in all cases, and when the general level of the mental tone is raised obsessions disappear (Janet), so that the bringing up of the general health to the highest possible level is the first thing. To this end simple physiological procedures, rest, full feeding, gentle exercise, massage, bathing, etc., should be instituted in every case. In obsessional states there is essentially a neurasthenia or "psychasthenia." In addition to rest and physiologic measures, mental rest by isolation, retraining of the patient, and later special mental exercises or gymnastics are advised. Judicious normal suggestion should be used, including such explanation of the patient's condition as may be adequate and tactful, pointing out that the symptoms are functional and will disappear. Suggestion under hypnotism he regards as rarely, if ever, justified. Psychoanalysis will probably not find a permanent place in therapeutics.

123 Easy Methods of Carrying Out the Principles of Aseptic Surgery. R. Reyburn, Washington.

119. **Acid Intoxication.**—Nichols discusses the physiologic chemistry of this condition and summarizes the four principal hypotheses as to the agents actually producing the toxic phenomena: (1) That the acetone bodies are themselves the toxic agents—which view he considers entirely inadequate; (2) that beta-oxybutyric and diabetic acids exert their deleterious action by virtue of their acidity; (3) that the harmful effects are due to the withdrawal of diminution of the bases of the body; (4) that the real toxic agents are some unknown precursors or associates of the acetone bodies. The condition, even in marked and serious form, occurs much more frequently than is generally realized, and he suspects that many obscure features that puzzle the clinician as in peculiar forms of indigestion, shock, uremia, etc., are dependent partly on an element of acidosis. The free administration of alkalies, while it produces no results in some cases, should nevertheless be tried in all severe cases. He recommends sodium bicarbonate 15 or more grams (225) grains daily. In addition, calcium carbonate, 3 grams (45 grains) daily, and sodium citrate, 5 grams (75 grains). When alkalies can not be given by the mouth they may be administered by rectum, subcutaneously or even intravenously.

131 Public Health Work and the Medical Profession. G. H. Kress, Los Angeles.

124. **Diseases of the Pancreas.**—Zerfing discusses the anatomy, histology and physiology of the pancreas, and summarizes recent work in pathology. He considers in detail acute hemorrhagic pancreatitis and chronic interstitial pancreatitis.

125. **Surgery of Pancreas.**—McReynolds refers to the most important and special indications for operative interference: 1. Injuries to the pancreas from stab or bullet wounds, or severe contusions in the epigastric region. 2. Inflammations—(a) acute hemorrhagic pancreatitis; (b) subacute pancreatitis; (c) chronic pancreatitis. 3. Pancreatic cysts.

127. **Gastrointestinal Diseases and the Pancreas.**—Visscher discusses the diagnosis of pancreatic insufficiency, and describes the laboratory methods of determining the missing functions of lipolysis, proteolysis, and amylolysis. As to treatment, here, as elsewhere, "pipes and tubes get dirty, stopped up, kinked, or compressed," and "nothing but a plumber will do"—to-wit, surgical help. But when the ducts are open and the gland is not degenerated, but only inactive, potentially active, then we can stimulate pancreatic functions indirectly, by hygienic, mechanical, hydriatic and electric measures. We have in the carbohydrates a physiologic stimulus to pancreatic secretion; but this must not be overdone by trying to make the gland secrete more than it can.

136 Crushing Injuries of the Extremities. T. H. Hancock, Atlanta.

135. **Sprains.**—After definitely excluding fracture in a recent sprain Toepel recommends: (1) Exposure for one hour to heat to relax tension. (2) Massage by gentle friction, gradually increasing in force, then gentle kneading, long-continued, beginning at a distance from the injury and gradually approaching it. End with palmar percussion. (3) Bandaging tightly with a wet bandage and applying ice bags to keep down inflammation, insisting on perfect rest with the joint elevated for from twelve to twenty-four hours. On the second day the treatment should be repeated, omitting the ice and adding passive circumduction and passive flexion and extension. On the third day resistive movements should be added. Activity should be encouraged between treatments after the second day and the bandage removed permanently on the third or fourth day. A light sprain takes from 7 to 10 days for cure, a hip or shoulder sprain longer, and it is safer not to use the latter for another week.

141. **Transillumination of the Eye.**—Fridenberg discusses transillumination of the eye by the Sachs transilluminator and the Würdemann transilluminator; he prefers the latter instrument. For some time he has been making transillumination a routine measure in ophthalmoscopic examination. A better reflex is obtained by applying the illuminating pencil far back near the equator of the globe, pointing it forward toward the anterior segment than under opposite conditions. The observer should look into the pupil in a line with the patient's gaze and not directly from in front as is usually done, unless the patient is looking straight ahead. He describes transillumination of the iris, the influence of the epithelial pigment layer of the iris on transillumination, as also the effect of opacities of the media, and suggests that the

ophthalmoscopic examination of the anterior segment of the fundus gives a much clearer and more brilliant picture if the retina anterior to the ora serrata is made self-luminous by applying the Sachs instrument to the sclera directly over the point to be examined.

8 Case of Dissecting Aneurism of Pulmonary Artery; Patent Ductus Arteriosus; Rupture into Pericardium. L. Durno and W. L. Brown.

3. Bacteriology of Cerebrospinal Meningitis.—Wilson describes a Gram negative diplococcus found in the feces of cerebrospinal fever patients. It superficially resembles the meningococcus, though quite distinct from it, and is shown by the following facts to have nothing to do with meningitis: 1. Typical meningococci were cultivated from the cerebrospinal fluid; and 2, the blood serum of these patients had a high opsonic index as regards the true meningococcus, but a normal index as regards this organism. Wilson describes the morphology, the cultural characteristics and the pathogenicity. He also describes a case of cerebrospinal meningitis due to infection with an organism of the *Micrococcus catarrhalis* class, which he describes in like manner, concluding with a résumé of the history of the *M. catarrhalis.*

4. Resection of Nasal Nerve for Hay Fever.—In a preliminary communication Yonge described a method of dealing with desperate cases of hay fever, based on the theory that the stimulant which induces the reflex manifestations observed in hay fever and in paroxysmal coryza is conveyed to the centers of the nasal nerve, which is thus the afferent path of the reflex. He discusses the distribution and functions of this nerve and describes the effect of cauterizing the nasal mucous membrane, and the effect of bilateral resection of the nasal nerve. Division of that nerve on one side abolished the intermittent nasal obstruction, with profuse hypersection on the side on which the nerve had been divided, whereas the disturbances continue to recur periodically in the opposite nasal cavity, as before operation. This led him in an intractable case to perform the following operation: Resection of the nasal nerve on the right side was first performed, chloroform anesthesia being employed. The nerve was reached by an incision at the inner edge of the orbit, commencing just above the inner canthus and extending upward and slightly outward for about two-thirds of an inch. The cellular tissue having been cleared from the inner upper wall of the orbit by means of a blunt dissector and the nerve located at the anterior ethmoidal foramen, the latter was separated from the artery and divided close to the foramen, about a quarter of an inch of the nerve being removed. Horsehair sutures were inserted and the wound was dressed with gauze and collodion. The stitches were removed on the fourth day. Resection of the nerve on the left side was carried out four weeks later. Two months after operation the paroxysmal coryza, sneezing and asthma had entirely disappeared, there was increased freedom of nasal respiration, and consequently the patient slept better. He had gained seven pounds in weight and the general health was manifestly improved.

7. **Gangrenous Strangulated Hernia.**—Corner reports the results of the treatment of necrosis of the bowel in strangulated hernia at St. Thomas's Hospital, between 1901 and 1905, numbering 30 cases. The methods used have been resection and immediate anastomosis, resection and enterostomy, and invagination. Comparing the first two methods, he considers that the line of treatment tends toward resection and anastomosis, notwithstanding the unanimity of abdominal surgeons as to the general danger of anastomosis in a bowel distended with septic fluid; but he points out that there is a great difference between cases in which the septic distention has taken place rapidly on an acute condition, as in strangulated hernia, and those in which it follows slowly in a chronic condition, such as carcinoma of the sigmoid. With regard to invagination, the two cases in which it was used proved very successful. It is applicable to small areas of necrotic bowel, and will be mainly useful for secluding "doubtful" bowel, at places where the bowel has been nipped, and for the patchy gangrene sometimes found at the apex of the strangulated loop.

10 Myalgia. J. R. Keith.
11 *Dangers and Evil Effects of Infant Binders. A. Waring
12 The Inky Polygraph. J. Mackenzie.
13 Plea for Habitual Performance of Autopsies in General Practice. J. T. Fox.
14 Traumatic Rupture of the Large Intestine; Operation; Recovery. W. H. Battle
15 Treatment of Fractures H. T. Gray.

11. **Infant Binders.**—Waring calls attention to the dangers of enveloping the infant's body "in countless bands, swathes and swaddling clothes" The dangers of constriction and increased intra-abdominal and intrathoracic pressure depend on: 1. The degree of constricting or binding force; 2, the extent of surface covered; 3, the time worn; 4, the health and power of resistance of the infant. He enumerates the following effects and conditions that may result from binder comparison: 1, Discomfort; 2, vomiting; 3, inguinal and umbilical hernia; 4, prolapsus ani; 5, thoracic deformities; 6, thoracic constriction in pulmonary diseases; 7, interference with cerebral circulation; 8, a contributory factor to the danger of death by overlying.

18 The Milk Problem, or the Production and Distribution of Pure, Clean Milk. J. C. Thresh.
19 *Empyema in Children. S. J. Ross.
20 Surgical Treatment of Chronic Dysentery. H. Steiner.

16. **Tuberculosis.**—Symmers gives a historical account of the progress of our knowledge of tuberculosis. Incidentally, he says that in conjunction with Sir William Whitla he has corroborated the findings of Vansteenberghe and Grysez, that ingested matter can pass from the intestines to the lungs. On introducing ground-up India ink through an esophageal tube, the carbon particles have been found in the lungs of an adult guinea-pig within four hours, the intestines and mesenteric glands offering little or no hindrance. In the case of baby guinea-pigs, however, the mesenteric glands act as a sieve and retain the offending particles.

17. Published in the *Intercolonial Medical Journal of Australasia*, February, 1908, and abstracted in The Journal, May 2, 1908.

19. **Empyema in Children.**—Ross sums up his remarks as follows: 1. If a child is brought on account of wasting, never omit to examine the chest. 2. If the child is too feeble to stand the operation of resection of ribs, remember that aspiration sometimes results in cure. 3. If we have a child under our care suffering from pneumonia whose convalescence is protracted, we must never forget to keep a watchful eye for the development of fluid. 4. If after drainage the patient's progress is unsatisfactory, we must remember that loculated collections of pus are not infrequent. 5. It is always necessary to examine the pus for the causal organism. If the pneumococcus is found the outlook is favorable. If the streptococcus, the injection of antistreptococcic serum will hasten convalescence. If the tubercle bacillus is discovered the outlook is very unfavorable indeed.

Glasgow Medical Journal.

June.

22 *Means of Observing and Recording the Efficiency of Urinary Discharge by the Urethra. A. N. McGregor.
23 Esophagoscopy. R. Fullerton.

22. **The Urinary Flow.**—McGregor details a method invented by one of his patients of gauging the rate of progress and the patency of his urethra during bougie treatment. The first micturition of the morning is most suitable as giving more constant results. The urine is passed into a four-ounce measure graduated in drams, a second being ready for instant substitution if necessary. The urine is allowed to flow into the glass, or glasses, for five seconds from the commencement of the act and then immediately stopped. The amount in drams is read off and noted on cross-section paper, having the numbers 0 to 32 from below upward on the left margin, and the dates along the base line. The dates of dilatation are marked, and the effect on the amount of urine passed in five seconds is thus charted. Experiments with normal patients showed a fairly constant figure, the average quantity passed being taken at 8 ounces. From 32 to 42 drams was found to be the normal amount passed in five seconds. In the case of strictured patients the charts appended to the article show that after dilatation there is a rapid rise in the amount passed in five seconds at the morning micturition; but they show also that overdilatation gives less satisfactory results than more moderate distention, for the gain more quickly subsides than in the latter case.

24 Unusual Pulmonary Cases. T. G. Moorhead.
25 Alcohol and Mental Diseases. W. R. Dawson.
26 *Duodenal Ulcer; Diagnosis and Treatment. A. B. Mitchell.

26. **Duodenal Ulcer.**—Mitchell answers in the affirmative the questions: 1, whether it is necessary and important to be able to diagnosticate duodenal ulcer with accuracy, and, 2, whether such diagnosis can be made with reasonable certainty. The reasons for the first question are the greater seriousness of duodenal than gastric ulcer, the greater liability to profuse and dangerous hemorrhage, the lesser likelihood of permanent cure by medical means in duodenal than in gastric ulcer, and the greater importance of surgical intervention. Duodenal ulcer can be recognized clinically, he says, with as great a degree of accuracy as gastric ulcer, gallstones or even appendicitis. The characteristic symptoms are: 1. Pain of a special type. 2. A feeling of fulness and discomfort after food, with eructations of gas, and generally some hyperacidity. 3. Local tendencies over an area just above and to the right of the umbilicus. 4. Hematemesis and melena. 5. Some degree of dilatation of the stomach exists in most cases from an early stage of the affection. He discusses these signs in detail. As to operation, his own practice is to do a jejunostomy (posterior operation when possible), and then close or partially close the pylorus by a few Lembert sutures. He reports seventeen cases of gastrojejunostomy for duodenal ulcer and nine cases of perforating duodenal ulcer, all terminating in recovery.

27 Congenital Circumscribed Alopecia. W. Dubreuilh and G. Petges.
28 *Treatment of Syphilids with Local Injections of Mercury. H. Hamel.

28. **Treatment of Syphilids by Local Injections of Mercury.**—Hamel advises local medication in ulcerative and destructive syphilids and also when the lesions are localized at an inconvenient point. He advises it also when general treatment is impossible or has proved ineffectual or if there are kidney, intestinal or gum affections. Sixteen cases are described with the technic followed. The best results were obtained with an isotonic solution of mercury cyanid, 1 to 2,000, with a little anesthetic. A very fine needle is inserted, slanting, at one or more points, and enough fluid is injected to cause considerable infiltration. He made from five to ten injections, as a rule, with or without general treatment.

33 *Traumatic Diffusion of Urine in Kidney Region. (Pseudo hydronéphrose traumatique.) Nové-Josserand and Ballivet
34 *Postoperative Parotitis. (Considérations cliniques et pathogéniques.) P. Soubeyran and A. Rives.
35 Non-existence of "Adenoma of Testicle" (L'adénome testiculaire existe-t-il et peut-il exister?) A. Branca and A. Bassetta.

33. **Traumatic Diffusion of Urine in Kidney Region.**—Two cases are described of traumatic pseudohydronephrosis, both in children. In 18 cases on record treated by puncture there were 4 deaths in the pre-aseptic era; in 4 cases further operation was required, and the other patients were all cured; the puncture had to be repeated from 2 to 8 times in all but one case. If the perirenal effusion is not very large and the functional disturbances not alarming, expectant treatment is advisable or puncture is repeated as indicated. If the effusion constantly recurs it is better to open the pocket and marsupialize. If the pocket is infected, a plastic operation should not be attempted and nephrectomy must be done. In one of the cases described a large incision with a counteropening in the lumbar region proved insufficient, and the child succumbed to sepsis.

34. **Postoperative Parotitis.**—Soubeyran and Rives relate a case personally observed and 4 others from Mauclaire's experience and summarize 85 from the literature. They ascribe the parotitis to diminished secretion of saliva and enhanced virulence of the germs in the mouth. In some of the cases the parotitis had been preceded by stomatitis.

June 2, LXXII, No. 22, pp. 581-613.

36 *Preventive Injections of Antitoxic Serum in Prophylaxis of Tetanus. L. Vaillard.
37 *Arteriosclerosis. Its Pathogenesis and Treatment. Lancereaux.
38 Jean-Jacques Rousseau et Desessartz. A. d'Espine.

36. **Preventive Injections of Serum for Tetanus.**—Vaillard discusses 31 cases on record in which tetanus developed after the prophylactic injection. In 10 cases the tetanus developed between the seventeenth and eighteenth and in 8 between the tenth and sixteenth days after the injection. He thinks that the serum ceases to be effectual after a week or at most two weeks, and consequently the above cases are outside the range of the immunity conferred by the serum. A second injection might have prevented the tetanus. In the 13 cases in which the tetanus developed between the second and tenth days, in 6 there had been inadequate dosage; in others the wound was merely dusted with dry serum. There thus remain only 5 cases in which the prophylactic injection proved actually ineffectual—an insignificant proportion in view of the thousands of preventive injections made since 1896 in all countries. The statistics in veterinary practice show good results, he says. In a recent series of 13,124 injections of horses none contracted tetanus. He suggests that possibly one reason for the better results in veterinary practice is that the veterinarian makes the injection himself. Another reason is that in case of disabling accident the horse is killed and the outcome of the serum is known only in the mild cases. The conditions consequently are not the same as in case of serious injury to man. Antitetanus serum is not bactericidal. Spores protected against the phagocytes can proliferate even when the blood is strongly antitoxic. This proves the importance of destroying the spores in the wound and suppressing all conditions favorable to their growth. The serum protects against the action of the toxin, but only for about a week. The first dose should be effectual; the ordinary dose should be doubled or tripled in case of severe traumatism. Phagocytosis is less active in muscle tissue, and the abundance of nerve elements favors the absorption and the passage of the toxin by routes where the antitoxin does not seem to be able to penetrate. When tetanus developed notwithstanding the preventive injection, its course was undoubtedly milder. He advises repeating the injection as needed, his practice being a primary injection of from 20 to 50 c.c.; with 10 or 15 c.c. every week afterward; in one case the tetanus developed nearly thirteen weeks after a single injection. Local application to the wound is effectual only when the serum is not drained away by the dressings.

37. **Arteriosclerosis.**—Lancereaux protests against the assumption that arteriosclerosis is an affection of old age. He has observed it frequently between 30 and 40, and has noticed that its course is more rapid in the comparatively young. The two main factors are gout and lead poisoning. Tobacco, liquor and alimentary toxemia have long been overestimated, he thinks, as factors in arteriosclerosis. They act only in case of a tendency to gout or lead poisoning. The practical result of his views is that members of families which display a tendency to gout should be treated early, seeking to modify that condition of the nervous system which predisposes to arteriosclerosis. He thinks that he has done good work in this line, although its very nature prevents conclusive testimony. He prescribes potassium iodid, from 1 to 3 gm. (15 to 45 grains) in twenty-four hours, continuing this for months and years with intervals of a week each month. He orders at the same time a drastic purgative to promote the elimination of the iodid. Hypertrophy of the heart with high arterial tension and nocturnal polyuria with lesser density of the urine are signs of diffuse arteriosclerosis. Brine baths, alcohol rubs and tepid douches, by soothing the nervous system, favor the elimination of waste. The practitioner should seek to ward off the impending uremia, asystole or cerebral insufficiency, and treat them with the greatest energy if already developed.

June 10, No. 47, pp. 369-376.

44 *Multiple and Recurring Patches of Gangrene on Arms and Foot. Dieulafoy.

40. **Symptom of Perforation of Appendix.**—Delbet bases the diagnosis of perforation on a single symptom, which he has found constantly in all his cases. After the first onset of symptoms the pain subsides under repose and ice, but suddenly a paroxysm of pain returns. Although it soon subsides again, this abrupt return of the pain, notwithstanding that no imprudence has been committed, is a sign of perforation, and he operates at once.

43. **Ethyl Chlorid for General Anesthesia.**—Lemaitre has been using for two years ethyl chlorid in all operations not

requiring more than two minutes, and as the first stage of chloroform anesthesia. He gives an illustrated description of the simple apparatus, mask and collapsible bag which is used for the purpose. He is convinced that this technic is the most rapid and, with the chloroform, is perhaps less dangerous than any other method for prolonged anesthesia.

44. **Recurring Patches of Gangrene.**—Dieulafoy reports a case in which a man of 30 consulted more than fifteen physicians and surgeons for recurring eschars on the left arm. The affection was diagnosed as neuritis, myelitis, etc, and all kinds of treatment were tried, including stretching the nerve Finally, he consented to have the arm amputated, but after a few months the patches appeared on the other arm and on the foot. After two and half years of this affection Dieulafoy decided that the man was malingering, and obtained a confession that he had made the sores himself with caustic potash. With the confession the obsession vanished He had no pecuniary motives for this conduct, and the case raises interesting questions in regard to legal responsibility.

50 Familial Gallstone Affections (Lithiase biliaire familiale) P Londe

46 **Pernicious Anemia.**—Labbé and Salomon declare that pernicious anemia is not a morbid entity but a clinical syndrome resulting from extensive destruction of blood with insufficient repair It is merely, they assert, the last stage of a symptomatic anemia These conclusions are based on the international literature, and on clinical and experimental research Six pages of bibliography are appended

48 **Severe Jaundice from Meat Poisoning.**—In the two cases reported the jaundice came on in the midst of health in young men, except that one in the past had been treated for dyspepsia and mild nephritis and his father for delirium tremens. After eating the spoiled meat, a few days of dyspeptic disturbances and pains were followed by severe illness with delirium, intense jaundice, filiform pulse and terminal coma in the first case. During the coma in the second case there was incontinence of urine and feces, but the kidneys worked so effectually, passing nearly 4 000 grams of urine a day, that the patient gradually recuperated after four days of coma and subcutaneous hemorrhages The soundness of the kidneys, re enforced by saline infusion, was evidently his salvation

51 *Characteristics of Venous Pulse in Hypertrophy of Left Heart Associated with "Kidney Heart and Aortic Insufficiency. (Caractères du pouls veineux dans les hypertrophies du cœur gauche liées au cœur rénal et à l'insuffisance aortique) L Bard

June 10 No 24, pp 277-288

52 Intrapelvic Saccular Dilatation of Uterus at Term B de Bovis

51. **Characteristics of Venous Pulse with Hypertrophy of the Left Heart.**—Bard gives a number of tracings in cases of hypertrophy of the left heart with kidney disease and aortic insufficiency. He shows that the special phases of the venous pulse reveal several important features of this condition. Accentuation of the presystolic wave, after acute nephritis not leaving any traces of albuminuria, is one of the earliest signs of later chronic nephritis As the characteristics of the venous pulse become modified in the various phases of the kidney affection, they throw light not only on the diagnosis, but also on the prognosis of the cardiac lesions The lengthening and the—at least apparent—anticipation of the systole of the auricles in nephritis and in aortic insufficiency, reveal the existence of changes in the habitual synchronous action of the auricles and ventricles from the disturbance in the usual course of the blood through the heart.

61 *Tuberculin Salve in Differentiation and Treatment of Lupus E Senger
62 Retrogression to Embryonal Conditions in Blood (Rückschlag in die embryonale Blutbildung) C. S. Engel.

61. **Tuberculin Salve in Lupus.**—Senger applies a 3 per cent. tuberculin-lanolin salve in local treatment of lupus. There is no general reaction, but the local reaction is like an explosion, he says The inflammation and suppuration that follow the application of the salve have a curative action, or at least prepare the soil effectually for phototherapy. He has been studying this technic for two years, and extols the manner *in which it cures the lupus or influences toward a cure,* especially when the inunction of tuberculin salve is supplemented by Roentgen exposures. He regards the reaction as specific, comparing it to the sudden chemical reaction between gunpowder and fire, or that between nitric and carbolic acids. The reaction stops abruptly at the edge of the lupous patch. The reaction also serves to differentiate a tuberculous or lupous lesion from ulceration of other origin.

72 Ring Bodies in the Blood in Anemia. (Ringkörper im Blute Anämischer) Gabriel

63. **Influence of Occupation on Size of Heart.**—Schieffer computed a normal standard for the proportions of the body and heart from an average of 56 healthy young recruits. Comparing this standard with 33 men accustomed to hard manual labor, 23 with light work, and 32 others who use the bicycle constantly, he finds that the heart enlarges in size as demands are made on it—a physiologic reaction to the stress Bicycling has the same effect as hard manual labor in this respect. ,The same conclusions apply also to the military service.

65. **Dyspepsia from Abnormal Fermentation in the Intestines.**—Meyer describes his experiences with 16 patients. The trouble is defective secretion in the glands of the small intestines, presumably of functional nature It may occur independently, especially in neurasthenic and anemic individuals, or it may be the result of a primary stomach affection. Abstention from carbohydrates for a time is generally sufficient treatment, with all vegetables passed through a sieve. Possibly lavage of the stomach, hydrochloric acid and massage may be required. (See abstract 74.)

67. **Intravenous Injection of Strophanthin.**—Hoepffner has made 78 intravenous injections in 34 patients, including 5 with pneumonia and 4 with tuberculosis. In these latter cases the results were only transient. The drug displayed the greatest efficacy in 8 cases of chronic nephritis with cardiac insufficiency In one of these cases 11 injections of 1 mg. were given in 41 days with complete subsidence of the extensive dropsy which had previously resisted all treatment.

The drug also proved beneficial in 2 cases of heart failure in meningitis and typhoid, also in 12 cases of chronic heart disease. He had 2 fatalities, and the injection was evidently responsible for one of them, he says. The patient had a severe chill an hour after the injection; it had been given for a severe uncompensated valvular defect. The chill was probably the result of bacterial contamination of the drug. The patient succumbed during the chill.

68. **Blood Findings at the Bedside.**—Wynhausen describes the findings in half a dozen cases of atypical leukemia and leukanemia in children.

69. **Pressure in Pleural Effusions.**—Weitz regards determination of the pressure as very important. It shows when to arrest the puncture, and is also useful for differentiation.

70. **Tuberculin in Leukemia.**—Weitz has found that tuberculin gives a transient improvement which may be found useful as a preliminary to other measures in treating leukemia.

80 Treatment of Fractures of Fingers. (Fingerfrakturen.) P. Ewald.

73. **Delivery Under Scopolamin-Morphin.**—Krönig believes that the modern woman has nervous exhaustion and loss of will power in the course of childbirth to an extent hitherto unrecognized, and that this tendency is constantly increasing, especially among the so-called better classes. Obstetricians who practice in the "West End" of Berlin state that they have to use forceps in nearly 40 per cent. of the childbirths. Everyone there agrees that the increase in the number of cases of puerperal fever is due to the increasing proportion of forceps deliveries. More and more is it demanded of obstetricians that they relieve or put an end to the pains of childbirth. He thinks that the nervous system of the modern woman is scarcely able to stand the stress of labor which is really not physiologic with her, as the nervous system is below par. That neurasthenia does not follow childbirth more frequently than it does is a matter for surprise. He is convinced that his technic of scopolamin-morphin "twilight sleep" answers its purpose of rendering childbirth entirely or nearly painless. He has applied it in 1,500 cases. In his last 500 one patient succumbed to hemorrhage from rupture of the uterus, the family refusing to allow an operation; one child died during delivery and 3 others in the first three days. He ascribes this low mortality to the benumbing of the respiration center by the trace of scopolamin which passes to the child and prevents aspiration of amniotic fluid, etc. This theoretic explanation is assailable, but the fact remains that with an experience of 1,500 cases the mortality of the children during and immediately after delivery is much less than it was before the scopolamin technic was introduced. Later reports from nearly 300 of the children show that the development in all respects has been normal. Everything depends on correct dosage and management, and years of experience have been required to attain the results reported. The supervision of the patient requires the most careful intensive attention. The woman must be protected against noises, bright light, etc. Great practice and skill are required for this technic. He has not found that it prolongs the birth process beyond its physiologic limits, even if it should lengthen it by half an hour he thinks that this might well be disregarded. The details of the technic used at the clinic were summarized in these columns March 7 and 16, 1907, pages 912 and 983, as published by Gauss.

74. **Tests of Intestinal Functioning.**—Schmidt uses a test diet for two or three days consisting of from one to three pints of milk, raw or cooked in the dishes, porridge, strained, one soft boiled egg, from 100 to 250 gm. soft mashed potato and 100 gm. white bread or its equivalent, with tea or cocoa in the morning, and, at midday, a quarter of a pound of finely chopped raw beef, browned a little on the outside but raw inside. The third day the stool is examined; scraps of connective tissue reveal disturbance in the gastric digestion. Of all the digestive fluids, only the gastric juice is able to digest raw connective tissue. The discovery of undigested connective tissue thus reveals some derangement in the functioning of the stomach, which may be responsible for a supposed intestinal trouble. He gives an illustrated description of his test of pancreas functioning by means of small cubes of fresh beef tied in a bag made of a circle of gauze. It is swallowed with the food. When the little bag is found in the stool the nuclei in the meat are digested out in normal conditions and nothing is left in the gauze but the tissue fibers. When the nuclei are retained unimpaired this is a sign of secretory insufficiency in the pancreas on a functional basis. The Cammidge test is rather a sign of destruction of pancreas tissue, especially fat tissue necrosis. Discovery of sago-like grains, representing the relics of potatoes, indicates disturbance in the digestion in the small intestine. This may occur alone, and suggest insufficiency of the intestinal secretion which breaks up starch, for neither the lack of saliva nor of pancreatic secretion leads to such losses of starch. One of the common consequences is abnormal fermentation in the intestines, revealed by formation of gas, acid reaction, lighter color and odor of butyric acid when the stool is kept in the incubator for 24 hours. Prolonged fermentation dyspepsia entails irritation of the intestinal mucosa, with secondary catarrh. *Treatment* consists in abstention from carbohydrates and treatment of any accompanying stomach derangement. His experience has been that the majority of the so-called nervous diarrheas are latent catarrhs. The nutrient medium determines the flora, not the reverse. In regard to constipation his research has shown that not only the water but also the dry substance of the total stools are much below the normal amounts. The constipation is due to the fact that the digestion is too perfect. The food is digested and assimilated too completely; there is not enough waste left to form a proper culture medium for the normal bacteria, and consequently there is no stimulus for natural peristalsis. Treatment should aim to supply substances to make the feces more bulky and moist, and this he accomplishes by having the patients take agar-agar regularly. The intestinal motor functions are stimulated by it without the least irritating action. The effect has been excellent, and confirms his theory in regard to the true cause of constipation. Increasing knowledge of the functional disturbances of the stomach has shown, he declares, that motor disturbances, aside from stenosis, are as a rule secondary, and it is more than likely that the same is true also of the intestines. The aim should be to separate the complicated chemistry of digestion in the small intestine and its disturbances into its single components. Functional tests with his "test diet" show that this is possible.

77. **Clinical Importance of the Sphygmobolometer.**—Schulthess relates his experiences and the results of examination of more than 100 recruits, 18 healthy nurses and 19 patients with heart affections. He thinks that this method of sphygmobolometry fills a long-felt want, as it allows the work of the left ventricle to be recorded in figures. It shows the relations and the differences between the pathologic and the normal systole and the varying behavior of the same heart under different conditions. The reaction of the heart thus measured in figures allows the effect of heart tonics to be judged with certain and objective findings, apart from the patient's statements or the pulse findings, and without waiting for the disappearance of signs of pronounced insufficiency.

90 *Failure of Calomel Salve to Protect Against Syphilis G Vorberg

82 **Sarcoma of Rectum.**—Exner reviews what has been written on the subject of non-melanotic sarcoma of the rectum and reports two cases This material shows that apparently harmless hemorrhoidal nodules may be the starting point for a sarcoma. Overlooking the malignant nature of the hemorrhoidal growth may have the most serious consequences, as in one of the cases reported In the other case the unusual toughness of one of the nodules led to its being examined under the microscope, with discovery of a small-celled, round-celled sarcoma. The patient is in apparently perfect health to date, more than a year since its removal. She had applied for relief from recurring hemorrhages from inflamed external hemorrhoids. The rectum was amputated; no metastases were found in it.

84. **Preparation for Laparotomy.**—Schwab regards general anesthesia as defectively conducted when the patient makes any retching movements Even if it does not come to vomiting, the retching not only brings danger of aspiration pneumonia, but has a very weakening effect besides. Consequently he believes in using plenty of the anesthetic to prevent any tendency to vomit Another prophylactic measure which does not receive the attention it deserves, he says, is thorough disinfection of the mouth Disinfection of the field of operation with benzin and iodin is the simplest, quickest and least depressing of all technics to date, he thinks He gives a sedative for the last few days before the operation, and insists on all present refraining from speaking during the operation or else wearing veils, even when they have nothing to do with the operation.

90. **Failure of Calomel Salve to Protect Against Syphilis.**—Vorberg has collected from various society proceedings a number of cases of the prophylactic use of Metchnikoff's calomel salve with disastrous results, although applied strictly according to directions.

100 Bolus in Treatment of Diphtheria Stumpf

91. **Experimental Research on Formation of Blood.**—Meyer's experiments demonstrate that degeneration of the spleen follicles can not be the cause of leukemia Consequently splenectomy is irrational They further show that the proliferation of marrow tissue in pernicious anemia is a reparatory process and not the cause of the anemia. Roentgen treatment of this proliferation of marrow tissue is therefore useless

94 **Congenital Syphilis of the Suprarenals.**—Esser reports three cases of inherited syphilis in infants in which the sole or predominant localization of the syphilis was in the suprarenals. Vomiting, colic and diarrhea, independent of the food, were the main symptoms. In Elasser's compilation of 549 cases of tuberculosis of the suprarenals, in 17 per cent. there was no tuberculous affection of any other organ, but in 43 per cent. there was chronic pulmonary tuberculosis. In both syphilis and tuberculosis the suprarenals can thus be the primary seat of the disease, possibly from intrauterine transmission of the infection. The suprarenals of syphilitic fetuses should be examined for spirochetes.

96. **Diagnosis of Incipient Tuberculosis of the Lungs.**—Ranke has been able to make a physical examination of the lungs of a number of persons succumbing to various nontuberculous diseases, the findings being controlled by autopsy not long after. He found ten cases in which the lungs showed traces of a small apical lesion Those about the size of a bean gave no clinical signs of their existence, but one lesion, about the size of a hazelnut, was recognized during life. The breathing sound was harshly vesicular, expiration prolonged, and the murmur changed more to the bronchial type. The infiltration in this case was manifested both by percussion and auscultation. His experience further confirms the diagnostic importance of the obscuring, the "veiling" of the inner margin. It is generally combined with dulness over the apex. His cases showed that distinct restriction of the field of resonance over the apex is the result of an effusion or of pleuritic thickening. Percussion of the lower margin of the lung and its excursion is an important link in the chain of symptoms, especially when positive. The diaphragm may be restricted in its movements, even in incipient tuberculosis, but this is not always necessary. In twenty persons examined there was no change in the breathing sound toward the bronchial type, and in none of these cases was any infiltration in the lungs discovered later. This confirms the importance of this physical sign for the diagnosis. In case of secretion in the bronchi the breathing sounds are harsh and jerking, with prolonged expiration This form of expiration is exclusively a symptom of secretion, and must be distinguished from the prolonged expiration with the tendency to bronchial breathing and its transitions into the vesicular—this being a symptom of infiltration, although both types may be combined. He found what he calls "unclear" breathing sounds (*unreines Atmen*) in three cases with pleuritic thickening, but no infiltration or secretion. This anomaly is noted especially in elderly people, but has no differentiating importance. Increased intensity in the inspiratory sound is ascribed in the text-books to catarrhal secretion. His experience has shown, however, that it occurs frequently when there is a tuberculous focus, as a sign of vicarious emphysema. Infiltrated parts are surrounded by a zone of more or less distended air vesicles, and this is the rule with apical cicatrices. He thinks it probable that this local emphysema is manifested by increased intensity in the breathing sounds He adds that the relative proportions between the signs must be borne in mind, citing as an example of the necessity for this rule a case of heart disease in which there was pronounced dulness over one apex, impairment of resonance, increased vocal resonance, and prolonged expiration but no vesicular inspiration. The lack of change in the inspiratory sound was all that prevented the erroneous diagnosis of a large cicatrix in the right apex. Autopsy showed extensive pleuritic thickening and reduced circulation in the apex, owing to an old thrombus in the pulmonary vein, but no signs of infiltration. This case teaches the importance of correlation between the symptoms for the diagnosis of tuberculosis.

98. **Cesarean Section and Spinal Anesthesia.**—Polano was able to render Cesarean section painless, in the four cases he reports, by the use of spinal anesthesia. The patients all had flat, rachitic pelves The four children were normal and lively, differing in no respect from spontaneously born children He believes that the children suffer from the general anesthesia in ordinary Cesarean section, and that this is avoided with spinal anesthesia The fact that the contracting power

of the uterus is independent of the anesthetized spinal cord was confirmed by the experiences in these cases. The uterus contracted at once as under normal conditions, and the loss of blood was slight, while the anesthesia was complete.

101. **The Blood in Meningitis.**—Zand concludes from investigations in 10 cases of epidemic meningitis, 2 of suppurative and 6 of tuberculous meningitis that high leucocytosis speaks against the tuberculous variety. When the case is progressing favorably, the number of leucocytes gradually declines even to subnormal figures. In the non-tuberculous forms the leucocytosis is predominantly in the multinuclear neutrophile cells.

102. **Dissecting Aneurism of the Aorta.**—Schede reports, with autopsy findings, a case of dissecting aortic aneurism in a woman of 70, and reviews similar cases on record In his case the dissecting aneurism had spontaneously healed enough to restore comparatively normal conditions, and it was an autopsy surprise.

109 *Alimentary Levulosuria. A. R. v. Sabatowski.
110 *Phloridzin Test of Kidney Functioning. (Phloridzinprobe.) V. Blum and H. Prigl.
111 Palpation of Appendix. T. Hausmann.
112 Means of Aborting Attack of Angina Pectoris and Paroxysmal Tachycardia. (Kunstgriff zur Unterdruckung der Anfalle von Angina pectoris und paroxysmaler Tachykardie.) M. Herz.

107. **"The Lymphatic Temperament."**—Bartel writes from Weichselbaum's Institute for pathologic anatomy at Vienna to announce certain conclusions in regard to the influence of defective development of the lymphatic system as encountered in more than 100 cadavers. Individuals with this hypoplastic constitution succumb between the ages of 14 and 25 in 56 per cent. of the cases, mostly to infectious diseases, especially tuberculosis, to which they oppose slight resistance Suicide, diabetes and nephritis, also abnormal pregnancy or eclampsia, are responsible for some of the mortality. Between 26 and 45, exophthalmic goiter, placenta prævia, ectopic pregnancy, atheroma and fatalities under anesthesia carry off 40 per cent. After 46, tumors are exceptionally frequent at all ages, especially glioma, teratoid, epithelial and connective tissue growths. The female sex predominates. He regards the fate of individuals with this hypoplastic constitution as a kind of natural filtering process, fully 56 per cent. succumbing before they reach the reproductive period. All were tall and well developed, even unusually plump in some of his cases, except for the narrowness of the arterial system, the "lymphatism," and the hypoplasia of the genitalia. The vulnerability may be due to some special weakness of the mesodermal layer. The glands in the neck and mesentery were always inclined to be large, and they cut like marrow; the thymus was always large, except in cases of chronic tuberculosis.

109. **Alimentary Levulosuria.**—Sabatowski calls attention to the alimentary levulosuria test as deserving wider application. Positive findings were obtained constantly in cirrhosis of the liver, while the findings were negative with nutmeg liver unless there were marked anatomic changes in the parenchyma. Positive findings are also the rule in infectious diseases, and in jaundice of infectious and toxic origin. Jaundice from obstruction does not give the test unless there are anatomic changes in the parenchyma. He has applied the test in 78 cases of liver affections, giving 100 gm. levulose in lemonade. Vomiting or diarrhea occurred in about 6 cases each in 120 tests. He believes that the levulosuria is independent of stasis of bile, but is a constant accompaniment of every severe liver affection, and may serve to differentiate an infectious process in the liver. In one case a tumor under the right costal arch suggested a liver affection, but the absence of alimentary levulosuria confirmed the assumption of a tuberculous process in the great omentum.

110. **The Phloridzin Test of Kidney Functioning.**—Blum and Prigl regard this test as much inferior to the indigo carmine test, as it has given contradictory findings in their hands. Delay in appearance of sugar in the urine after administration of the phloridizin, beyond the fifteen-minutes interval accepted as the normal standard, is not a certain sign of anatomic or functional lesion in the kidney.

June 6, XXXV, No. 23, pp. 697-728.

113 *Method of Expelling the Blood from the Lower Half of the Body. (Künstliche Blutleere der unteren Körperhälfte.) Momburg.
114 Technic of Esophagoscopy. Kölliker.

113. **Method of Expelling the Blood from the Lower Half of the Body.**—Momburg has been studying for some time means to render operations as bloodless as possible, and has become convinced that it is possible and harmless to cut off from the circulation the entire lower half of the body. He accomplishes this by drawing a belt so tight that the pulsation in the femoral artery can no longer be detected. A rubber tube nearly an inch in diameter is stretched to its utmost length and then wound from two to four times around the waist of the reclining patient, midway between the crests of the ileum and the costal arch, and fastened. This exclusion of half of the body from the circulation is very simple; it answers the purpose perfectly, and does not injure the intestines or ureter, as the thick abdominal walls spread the pressure; the other abdominal organs lie outside the zone of compression. There does not seem to be any disturbance in the heart action when the patient is thus belted in. The spinal cord is not affected, as the compression is below its lowest point. The conditions are different in animals, but even with them the use of a broad band or interposition of a strip of felt allows the compression to be maintained for an hour and a half without apparent injury. When the compression is to be removed he applies a constricting band to each thigh and raises the legs so that the restoration of circulation occurs gradually, as otherwise there is transient disturbance in the heart action. The respiration was never affected. He has applied this technic in two cases, besides tests on healthy men, who bore the compression without an anesthetic for five minutes. In one of the clinical cases the elastic tube was in place for 43 minutes and in the other for 18 minutes. In the last case a sarcoma of the hip joint required exarticulation, which was done under spinal anesthesia without loss of blood, as the lower part of the body had thus been shut off from the circulation.

119 Measurement of Gravid Uterus. (Messung des graviden Uterus) Piering.
120 Combined Instrument Sterilizer and Table (Vereinigung von Instrumentenkocher und Instrumententisch.) F. Stahler. (Siegen).

115. **Scopolamin Morphin in Obstetrics.**—Mayer has followed Gauss' technic in 50 obstetric cases. His impressions

are that the procedure does not quite attain its purpose of relieving or banishing the pain of labor, and that the indications for this technic are comparatively limited, while the occasional by-effects and disturbances stand in the way of its unconditional recommendation. He reiterates that this scopolamin-morphin method should never be applied outside of an institution where constant supervision of the parturient by a physician is possible. The general practitioner can not expect to apply this technic in his practice.

118. **Amaurosis in Pregnancy.**—Holzbach reports a case of amaurosis gradually developing in the course of pregnancy. The first signs of optic neuritis were noted about the fourth month; both eyes were affected and external causes could be excluded. The optic nerve was atrophied when the patient was first seen and the indications for interruption of the pregnancy were beyond question. Sight began to improve at once, and within two weeks vision was restored in the right eye. The other eye was first involved and the nerve was atrophic beyond relief. The woman was an x-para of 37, with eight children, and he deemed it necessary to insure future sterility by an operation on the tubes. The case confirms anew the importance of immediate interruption of the pregnancy in case of optic neuritis from this cause.

124 Cutaneous Serum Reaction in Syphilis. (Fenomeni di allergia nei sifilitici.) E. Tedeschi.

123. **Pyretic Phase in Action of Quinin.**—Mircoli reports experimental research which corroborates the views of the Roman school in regard to the best technic for administration of quinin. If given too soon either it has no action or the pyretic phase of the quinin influence will be superposed on that of the malaria. Given too close to the paroxysm the quinin does not have time to manifest its antipyretic action. The sensitized organism is liable to react with the febrile phase, and the febrile condition is magnified by the combination of the malarial and quinin pyresis. In the subcontinuous form, lacking the control of the thermic cycle, if quinin is given by routine it may induce continued high temperature from the thermic reaction to the quinin by the soil sensitized by the malaria. The "Roman" technic is the administration of a single dose of 1 or 2 gm. (15 or 30 grains) of the quinin salt a few hours before the paroxysm.

130 *Parotitis from Pneumococcus Infection. E. Bargellini.

128. **Raynaud's Disease and Exophthalmic Goiter.**—Piazza has recently observed a case of this combination in a young woman. The first symptom of Raynaud's disease appeared at the age of 6, and progressed to trophic disturbances. The symptoms of exophthalmic goiter appeared about puberty.

129. **Prostatectomy in Septic Cases.**—Cassanello's patient was a man of 63, with complete septic retention of urine, enormous distention of the bladder, and serious general intoxication. Suprapubic cystostomy with local treatment of the urinary passages improved conditions to such an extent that perineal prostatectomy could be successfully performed a month later.

130. **Parotitis from Pneumococcus Infection.**—Bargellini reports three cases of pneumonia in which bilateral parotitis developed toward the crisis. In one case the process progressed to necrosis of the gland. Streptococci could be cultivated from the pus, after the incision, and healing was not complete for more than a month. The process healed in the second case immediately after evacuation; in the third case the process subsided spontaneously.

DISEASE OF THE CEREBRAL VESSELS, WITH ITS PROBLEMS IN DIAGNOSIS.[*]

WILLIAM ALEXANDER JONES, M.D.
Clinical Professor of Nervous and Mental Diseases, College of Medicine and Surgery, University of Minnesota.
MINNEAPOLIS.

Diseases of the arterial system in the brain often give rise to a misleading and confusing chain of clinical symptoms.

Not infrequently these symptoms are almost identical with those of well-known diseases, such as tumors, abscesses, cysts, and hemorrhages. The diagnosis is, therefore, empirical or impossible, particularly if no gross evidences of disease are found in accessible or palpable vessels.

Changes in the vessel wall may be dependent on a defective development of the media, which leads to aneurismal pouches, minute, moderate, or large. Atrophy, inflammation, or degeneration follows wasting disease. Acute arteritis from infective processes or intoxications, extensions of disease, septic or otherwise, from adjacent structures, and from external injuries, have been clearly demonstrated by bacteriologic and histologic investigations. Thromboarteritis, in which the brunt of the attack is sustained by the intima and media, may result in the organization of a thrombus and the partial or complete obliteration of the vessel lumen. Arteriosclerosis, a circumscribed or diffuse thickening of the arterial walls, especially of the intima, secondary to certain inflammatory or degenerative changes in the media, covers such a broad field and is so well appreciated that further description is unnecessary.

The following cases represent a form of vessel disease in which there are fairly well-defined focal manifestations, which might easily fall under the head of brain tumor or other gross disease, and yet not represent the ordinarily recognized forms of cerebral arteriosclerosis. These cases also illustrate disease of the arteries of the brain without other marked evidences of general vessel degeneration.

CASE 1.—L. W. R., male, aged 45, married, telegrapher.

Family History.—Father died of bronchitis at 48; mother died of old age at 77. One brother and one sister are living and well. One sister is dead; cause unknown. Two sons and a daughter are living and well, except that all are somewhat nervous.

Personal History.—General health is fair. He can not recall any severe illness. He had gonorrhea years ago; syphilis, he denied. He had been twice married; neither wife had any miscarriages. Twenty years ago, the patient fell, striking his spine, and sustained some sort of injury, which necessitated his being kept in bed in a prone position for ten weeks. There was apparently a complete recovery.

Present Disease.—Ten years ago he began to have jerking in his legs at night with occasional cramps. This condition grew worse, and seven years ago his arms also began to jerk, but after a time he improved in this respect, and his upper extremities are no longer affected, though he still has slight jerking in his legs, both day and night. About ten years ago he also began to lose the power of hearing in the left ear, and at the end of two years the loss was complete. A few months later, hearing in the right ear became dull, but he was still able to continue his work as a telegrapher until one morning he woke to find himself absolutely deaf. From that time till two years ago, he did clerical work. Ever since his deafness appeared, he has had noises in his head. There is constantly present a sound as of singing insects, and, in addition, there is at times a roaring like the fall of water, sometimes near, again far away, and at times there is a noise like that of the intermittent tooting of an automobile horn, sometimes high and sometimes low in pitch. This latter sound occurs only when he is nervous or worried. Sexual power has been weak for six years, and for the last year wholly gone. Two years ago he lost control of his bowels and bladder. After a time, this was regained, but is now again lost. During the last five years he has had attacks of dizziness from time to time, possibly due to digestive disturbances. When he becomes dizzy, he is also nauseated unless he assumes a recumbent posture. If he lies down, the nausea goes away, and if he closes his eyes, the dizziness also disappears. During the week before consulting me he had been dizzy always when rising from a recumbent posture. Four years ago he began to shuffle his feet when walking, and of late his gait is decidedly staggering. He still writes fairly well, but at times his hand jerks and the pen drops. He is confined to the bed and a chair practically all the time.

Physical Examination.—He is a medium-sized man, fairly well developed and nourished; skin, healthy in appearance; muscles, small. Temperature, 98.6 F.; pulse, 64, regular and normal in volume. Examination of heart and lungs is entirely negative. Radial and temporal arteries are soft. Abdominal organs are normal except for a considerable amount of gas in the stomach and intestines.

Urine: Clear, dark amber, strongly acid; specific gravity, 1.028; trace of albumin; no sugar; cylindroids and considerable mucus.

He complains of vertigo when he first rises, and says this is not worse when it is dark. He has an occasional slight headache—never any that is severe; no tenderness about the head. The eyes are deep set. There is no conjunctivitis, ptosis, lagophthalmos, nystagmus, or strabismus. Vision is fair. Examination of the ears is negative, except that he is absolutely deaf. Taste and smell are normal. No disturbance of cutaneous sensibility for touch, pressure, pain, or temperature can be demonstrated. The patellar reflexes are both increased; no ankle clonus. Marked Romberg sign is present with moderate ataxia in the hands; no Babinski sign. The muscles are all small. Those of the upper extremities are soft and flabby; those of the lower limbs are spastic; no atrophies; no fibrillary twitchings. He walks with a distinctly spastic, staggering gait.

Mental Condition.—His expression is sad but intelligent, and he has no peculiarities of dress or attitude. He is oriented as to time, place, and surroundings comprehends what is said to him and answers relevantly. His memory is good. He is evidently much depressed and worries a great deal because he is unable to get about. At times he is extremely irritable, no hallucinations or delusions.

---

[*] Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Course of Disease.—Oct. 26, 1907. He has been failing since last note. He says that he is losing flesh and that the power in his right hand is failing, though examination does not confirm the latter statement. Suffers severely from constipation and passes a limited amount of urine. His feet and legs become cyanotic and swollen if held in a dependent position. Almost ever since the last note, he has had a free flow of saliva, which, if swallowed causes vomiting. He has a bitter taste in his mouth and has a constant feeling of distention and slight pain in his stomach. Taking food relieves this for a short time, but afterward seems to make it worse. Teeth are not tender, and gums are perfectly normal. Right pupil is a little larger than the left, both react normally for distance but sluggishly for light. Patellar reflexes are increased, no ankle clonus. He thinks that his eyesight is worse, and he is sure that he does not see so well during the dizzy spells as at other times. He says that he suffers greatly from mental distress.

Nov. 14, 1907. Much of the time the patient is extremely irritable and depressed. He walks with increasing difficulty and thinks that his eyesight is failing. He has no headache. The flow of saliva decreased for a time, but is again excessive.

Nov. 18, 1907. Dr. William R. Murray examined his eyes to-day and reported: "Lids and external ocular muscles normal. Cornea normal. Iris normal, reacts to light and convergence. Crystalline lens normal. Optic discs normal (lamina cribrosa prominent). Retinal arteries slightly contracted and pale, otherwise normal. Fundi show no pathologic changes. Visual fields (roughly) appear normal. Vision (R. and L.) for distance good. Reads fine print at ten inches. Examination of eyes negative."

Dec. 13, 1907. The man constantly complains of being weak, can not sit up except for short periods, he scarcely ever suffers from vertigo now. He has no pain except an occasional slight headache. Expression is bright. Sensibility to pressure and pain are about normal in upper part of body, but distinctly impaired in the legs and lower abdomen. Deep reflexes in the upper extremities are about normal, but are much increased in the legs. There is more or less spasticity everywhere, but especially in the lower extremities. No ankle or patellar clonus. No fibrillary twitching is noted; no contractures. There is no atrophy of tongue. He is still spitting very freely.

May 27, 1908. The man is in practically the same condition except that his ataxia is greater.

CASE 2.—Male, aged 48, married, train dispatcher, was seen June 14, 1907.

Family History.—Father died at 66 of kidney trouble, he had been a heavy drinker. Mother is living at 76 and well. One brother died of dysentery, and one brother drinks to excess. The maternal grandfather died of paralysis. There is no other nervous or mental trouble in the family.

Personal History.—General health in early life was fair. He had typhoid in childhood and gonorrhea at 17. Syphilis was denied. He was very ill with mountain fever twenty-four years ago. At different times he had a number of abscesses. He drank some every day, but rarely to the extent of being intoxicated. He used tobacco to excess habitually, his cigar bill amounting to $35 a month. He was married at 22. His wife has never been pregnant. He has never been injured.

Present Illness.—About twenty-four years ago, when excited over a little family trouble, he had an attack of jerking of all the muscles, lasting one-half hour. A second similar attack, only more severe, occurred seven years ago, and again during a family quarrel. It lasted one hour, and was not accompanied by unconsciousness. He did not fall, but was lying down at the time. For the last sixteen years he has been failing in health, and fourteen years ago he noticed some unsteadiness in gait. This latter has gradually grown worse since. Sixteen years ago he first complained of the wind and the pillows hurting his ears, and not long after that he began to slowly lose his hearing. The explosion of a cannon cracker is thought by the family to have hastened the latter. The trouble began in the right ear, and eight years ago the left also began to be affected. Eighteen months ago the right ear had become absolutely deaf and eleven months ago he suddenly lost hearing completely in the left ear, the change occurring within a few hours. From the outset of his ear trouble, he was greatly bothered by noises in his ears, a constant roaring with intervals of the sound of blowing whistles and the tooting of engines. These have continued ever since. On one occasion, since he became deaf his wife dropped her scissors and made considerable noise. He threw down the paper which he was reading, said he must have dropped his knife and began searching for it. He also said that at times, when holding his watch in hand, he could hear it ticking. His ataxia is now so great that he walks only with the assistance of a cane and, even then, with a distinctly staggering gait. His sexual power has been failing for sixteen years and for one and one-half years he has been entirely impotent. He is much constipated and for several years has often gone from seven to ten days without a bowel movement. For the past year there has been some loss of bowel control. Four years ago his urine began to dribble at the end of urination, and for three years he has had no control whatever of his bladder. There has been a tremor of the hands for years but not of such extent as to interfere with his writing until recently. About four years ago he had some attacks when his head would fall to one side or the other, and he would be unable to control it. These were of very short duration. He has had lumbar pain at times, but no headache. He always has vertigo if he moves suddenly, and frequently at other times also. He sleeps fairly well, but often talks in his sleep and sometimes very loudly. He is a little more querulous and nervous of late, but there was no distinct mental change previously.

Physical Examination.—He is a rather large man, fairly well developed and well nourished. Muscles are of fair size but flabby. Temperature 98.4 F.; pulse 80 and of normal quality. Lung examination is entirely negative. He has no cough. Apex beat of heart is slightly outside the normal line; no murmurs. There is a moderate degree of thickening of the radial and temporal arteries. Abdominal organs are apparently healthy. Sexual apparatus is normal.

Urine: Clear, amber, acid, specific gravity 1.024, no albumin; no sugar. Microscopic examination is negative.

He has an anxious, worried expression, does not complain of pain. Eyes are bright, both lids droop slightly and equally; there is moderate arcus senilis. There are no ocular palsies, no double vision, no nystagmus. Pupils are equal and react sluggishly to light, fairly well as to distance. Vision is good. Ophthalmoscopic examination is negative. He is absolutely deaf. Taste is normal, but smell is very much impaired possibly on account of a prolonged condition of catarrh. There is no disturbance of sensibility to touch, pressure, or pain. The deep reflexes of the arms are increased, and of the legs very much increased, no ankle clonus. Babinski sign is uncertain. Abdominal and cremasteric reflexes are normal. There is a fairly well-marked tremor of the extended fingers, no paresis or paralysis of the face or extremities.

Course of Disease.—At the time of his examination he was advised to go to a hospital but he declined to do so and remained for four days at a hotel. On July 8, while sitting at dinner, he suddenly became unusually dizzy. With assistance he was able to get to his room where he lay down on the bed. Shortly after he began to scream loudly and continued this for some time, but when seen one hour later he was lying in bed in a stuporous condition. He was transferred to the hospital where his temperature was found to be 98.2 and his pulse 84. The next morning the following conditions were noted:

He is conscious, but has a dull, heavy look and responds slowly to whatever is said or done. Is distinctly emotional. When questioned as to his experience of the preceding day he says that while seated at the table he experienced an unusual sensation in his head. This became gradually more pronounced and he feared that he would die. Says he screamed in order to obtain help. He can not describe the sensation in his head other than to say that it seemed like an 'unusual commotion.'

His temperature has ranged from 99.6 to 102.2 F., and his pulse from 100 to 110. There is some paresis of the left face, including a distinct drooping of the left lid. He appreciates touch in the left face but not the pricking of a pin. Tongue can be protruded straight. There is nystagmus of vestibular type with quick component upward and to left. Vision is very bad, probably on account of nystagmus. He has a constant sense of dizziness even in the recumbent posture. There is no ocular palsy. He can not swallow, and there is no movement of the throat on the left side. Deafness is complete. Apparently there is no disturbance of sensation in arms or body. There is possibly numbness in the right leg. Both knee jerks are exaggerated; double ankle clonus; no Babinski sign.

July 10, 1907: He has been failing since yesterday. Temperature dropped from 100 to 103.2 F., and pulse from 106 to 132. Nystagmus continues with some tendency to a rotary movement. He is very dizzy. Pupils react to accommodation and slightly to light. There are no ocular palsies. Left face is still numb and shows some motor impairment. He can not swallow and there is no movement of the left side of the throat. Left hand is very ataxic. No abdominal or cremasteric reflex is obtainable. Both knee jerks are exaggerated and right leg is rigid. Ankle clonus is present on the left side; no Babinski sign. He is unable to retain urine. He complains of no pain except slight backache. He died at fifteen minutes past midnight.

Autopsy.—The postmortem was made the next day at noon.

Macroscopic Appearance: There are some adhesions at the apex of the right lung. Both lungs are congested and edematous and the bronchi are full of mucopus. There is a beginning pneumonia in the left lower lobe. Heart is moderately enlarged. There is an old endocarditis and a moderate degree of atheroma of the aorta. Liver is normal. Spleen is soft. Left kidney is normal in appearance. The right kidney shows marked atrophy and hydronephrosis. The ureter also is enlarged, but shows no constriction at any point, and there is no indication of distension of the bladder. Prostate is normal. The calvarium is very thick, especially anteriorly. Dura is not adherent; the pia-arachnoid is thickened and opaque, especially along the larger vessels, but is not adherent. There is no atrophy of the brain substances. Ependyma is normal. All the large vessels at the base of the brain are very much diseased; they are increased in diameter; the walls, except in the region of the aneurismal dilatation, are much thickened and show many patches of distinct nodular sclerosis. The basilar artery is almost uniformly distended and measures a little over one cm. in diameter. Its walls are thin and almost translucent, except at a few small points. The left vertebral artery is moderately enlarged; the right is greatly enlarged, and at the point of junction with the left measures 0.8 cm. in diameter. The right inferior cerebellar artery has three distinct saccular aneurisms in its course, the largest measuring 0.7 cm. in diameter. The left inferior cerebellar artery has one small saccular aneurism and one rather fusiform aneurism, the latter measuring 1.5 cm. in its greatest diameter. This entire vessel and its branches for some distance are completely obstructed by blood clots. There is a well-marked extravasation of blood into the pia-arachnoid in the region of distribution of this vessel. The left anterior cerebellar is very small and not aneurismal; the right, also small, is not dilated. The right and left posterior cerebral arteries are very much sclerosed, the left having two small saccular aneurisms, and the right one aneurism. All the other vessels, at the best, are very much thickened, and at points show irregular dilatation, but none have any distinct aneurismal formation.

Microscopic Examination: On section and microscopic examination of the vessels the intima is found greatly thickened in places, with well-marked areas of degeneration. There is very little elastic tissue in the intima. The media in many places is thin, and this is particularly true in the region of the aneurisms where it is almost wholly absent. The elastic tissue of the media is much broken up, and there is also well-marked round-cell infiltration of this coat, as well as of the adventitia. The thrombus is infiltrated with leucocytes. Section of small vessels from the cortex shows the ordinary changes of arteriosclerosis rather well marked.

Case 3.—Male, aged 48, married, farmer, referred to me by Drs. Kilbride and Kelly of Canby, Minn.; was seen Dec. 16, 1907.

Family History.—Father died at 75 of paralysis; he had been temperate. Mother is living and well at 78. One brother died of nephritis at 40; one sister of tuberculosis and one sister of tuberculosis and nephritis. Four brothers and two sisters are living and well. The patient is married and has had six children, one of whom died in infancy; the others are well. There is no nervous or mental trouble in the family.

Personal History.—He was sickly in infancy, but after that period his general health was very good. He can not recall any severe illness at any time in his life. He has had occasional light attacks of rheumatism. Venereal diseases he denied. He has been temperate in the use of alcohol. Fifteen years ago he had a fracture of the right leg, which healed readily.

Present Disease.—Apparently he was perfectly well up to six months ago. At that time was working in the field and struck his left hand, just above the knuckle of the forefinger, with a wrench. The injury was slight, causing a moderate flow of blood, but no great pain. He continued at his work for a time, but at noon, when washing away the blood from the hand, he noticed a twitching of the first two fingers. This was slight, but not under his control. For three weeks longer he continued at his farm work, and during this period the twitching spread slowly to other areas. It was always worse when he was excited, and at such times appeared in parts which were entirely quiet when he was calm. The movements involved the left arm, shoulder, and neck, in the order named. Then the left foot and leg became affected, and when seen, Dec. 16, 1907, six weeks after the onset, there was twitching of the whole body, but more pronounced on the left side. He walked with difficulty and could scarcely button his clothes, especially if at all excited. He said that he had had vertigo at times for the past year. He was easily confused and cried at times.

Physical Examination.—He is a medium-sized man, fairly well developed and nourished. Heart and lung examination is entirely negative, except that his pulse rate is 88. There is a moderate degree of thickening of the radial and temporal arteries. His bowels move regularly and are entirely under his control, but he can not hold his urine so long as he could formerly. Sexual power is somewhat impaired.

Urine analysis is negative.

He has a rather dull, heavy expression, and complains of being weak. He has frequent attacks of vertigo, but can not associate them with any special time or act. He says that he has no pain. There is moderate arcus senilis but no ptosis, lagophthalmos, nystagmus, or strabismus. Vision is good with the aid of glasses. Examination of eye-grounds is negative. Thre is no defect of hearing and he has no subjective sounds. Sensation for touch, pressure, pain, heat, and cold is normal in all parts of the body. The patellar and Achilles reflexes are increased on both sides, but more so on the left. Ankle clonus is present on left side, but not on the right. There is well-marked ataxia in both upper and lower extremities, more marked on left than on right. All the muscles on the left side are spastic; there are no vibrillary twitchings. There is a constant, well-marked, fine tremor in left arm and hand, and at times this is seen in all parts of the body. It is increased by excitement or movement and is always worse on the left side. There is some incontinence of urine; none of feces.

Mental Condition.—Expression is dull and heavy. He has no peculiarities of dress or attitude. He talks but little and then only in response to questions. Is fairly well oriented as to time, place, and persons. His memory is much impaired, and he is slow to comprehend what is said to him. Often even a simple question must be repeated two or three times. His answers are only fairly relevant. He realizes that he is ill, but has no real insight into his mental condition. There are no delusions, illusions or hallucinations.

Course of Disease.—He was sent to the hospital and placed in bed. The next day his movements seemed about the same as when first examined, but the spasticity on the left side had increased and at times was much worse than at others. Occa sionally he was restless and, in an aimless sort of way, kept trying to get out of bed. His temperature was normal, but the pulse ranged from 72 to 96. There was involuntary urination. Two days after admission he had two convulsive seizures, the first one lasting eight and the second five minutes. The movements involved the entire body, but the left side more than the right. The next day he had another seizure of the same sort. The rigidity of the body was constant and much greater than on any other previous occasion. The left hand was tightly clinched. He swallowed with difficulty and was much more stupid. Temperature in the evening was 99.6 F.

December 20: There was not much change except that he was worse mentally, but on the following day he became partially paralyzed on the left side, and the right side became more rigid. His temperature was normal, but the pulse was 108 and weak.

December 23: He was quite unable to swallow, his stupor had increased, the paralysis on the left side was complete and the rigidity on the right side was much worse.

December 25: The following notes were made on this date: His expression is very dull. He talks little and only in whispers. Eyes are open, no ptosis or strabismus. Pupils are equal and react normally for light and distance. Tongue is dry and coated, protrudes slightly to the right. Right arm is rigid and strongly flexed, the fingers being drawn firmly into the palm. Right leg is extended and spastic, but less so than the arm. Left arm and leg are slightly spastic and almost completely paralyzed. The twitching is marked in the right hand, leg and foot; very slight in left hand and foot and, in the hand, is confined almost entirely to the thumb and forefinger. At times there is slight twitching in the right upper lip. He can move the right arm and leg but slowly and with difficulty. On the left side there are ankle clonus and greatly increased patellar reflex. On the right side there is no clonus but the patellar reflex is increased. Achilles jerk is increased on both sides. The head is distinctly drawn to the right side, though the muscles on both sides of the neck are firm. The left pectoral muscle is moderately contracted; the right firmly so. The right rectus abdominis is very firm; left flat. No abdominal reflex can be obtained on either side. Cremasteric reflex is absent on the left and slight on the right. There is involuntary passage of urine and feces. On account of his mental condition, it is impossible to determine anything as to sensibility. Pulse is weak and in the neighborhood of 120.

December 26: He was unable to swallow and was fed by nasal tube. Pulse ranged from 120 to 128, and was very weak and irregular. The right side had also become paralyzed. He was constantly in a condition of stupor. He died December 27, apparently from progressive failure of heart and respiratory action.

Postmortem Findings.—Dura is not adherent and is normal in appearance. Pia-arachnoid is thickened and very edematous in many places, not adherent to the brain. All the pial vessels are much distended with blood. The arteries at the base are thickened but uniformly so, and there are no calcareous plates. The right vertebral artery, at about the level of the first cervical nerve, shows a well-marked fusiform aneurism, 0.75 cm. in length and about 0.33 cm. in breadth. Almost directly opposite there is a saccular aneurism of the left vertebral 0.4 cm. in diameter. There is a moderate degree of atrophy of the cerebral substance in the anterior part of the brain. Section shows nothing except a general condition of hyperemia. Ependyma is smooth. On microscopic examination of the vessels there is a thickening of the intima and of the media with considerable increase of the elastic tissue.

The literature covering these specific findings is not very satisfactory.

The brain-tumor symptom-complex of arteriosclerosis is mentioned here and there by various writers, but no one author has given it his undivided attention. The majority of writers describe conditions under a general head and designate all vessel changes as arteriosclerotic.

Practically all cases reported seem to have ended by rupture of the vessel, with the usual manifestations of apoplexy. In Case 2 the patient died from obstruction of the circulation in the cerebellum and brain-stem. In Case 3 the patient died from rather uncertain causes. The most evident postmortem finding, other than the vessel changes, was edema.

Mummert[1] calls special attention to the rarity of cerebellar aneurisms.

Rindfleisch[2] speaks of the rarity of cases of aneurism of the basilar artery seen clinically, often symptomless until rupture occurs and then mistaken for ordinary apoplexy. If symptoms are present during life, a diagnosis of brain tumor is most commonly made.

Saathoff[3] refers to the position of the basilar artery whereby it is frequently exposed to undue pressure from indirect injuries.

Grunwald[4] gives considerable attention to the differential diagnosis of disease of the vessels at the base of the brain from other conditions with which it is likely to be confused.

Joseph Collins[5] has writen an exhaustive treatise on the different phases of cerebral arteriosclerosis, in which he refers to the brain-tumor symptom-complex.

Fisher and Brooks[6] discuss the relation of arteriosclerosis to diseases of the nervous system, but do not refer to aneurisms or other gross lesions of the basal vessels.

Bramwell[7] covers the field of intracranial aneurisms and reports cases with focal manifestations, but does not refer to cerebellar lesions or symptoms.

Barrett[8] has contributed an excellent article on the histology of cerebral arteriosclerosis with its clinical signs.

DISCUSSION.

Dr. H. A. Tomlinson, St. Peter: I have the records of about two hundred and fifty cases among the insane, and about thirty others, with regard to the postmortem findings in the cerebral blood vessels. My attention has been called particularly to the significance of the interference with the egress of blood from the brain, and I find that but little attention has been paid to this aspect of the subject. In the average individual, after 35 years of age, there is some piadural adhesion at the vertex, interfering with the emptying of the pial veins. In the defective and the degenerate, the tendency is for these adhesions to extend forward, finally involving the drainage of the area of the frontal lobes particularly. On account of the peculiar arrangement of the outlet of the pial veins into the sinus, the narrowing of the lumen of this outlet is a cause of serious obstruction; while the piadural adhesions along the median fissure, and at the base, interfere with lymph drainage. Therefore, aside from the diminished blood supply, resulting from the arteriosclerosis, there are the factors of the retained waste products, and the mechanical effect of lymph accumulation in the arachnoid space.

I have been interested to note two apparently different types of degeneration in the cerebral vessels: the one the usual productive periarteritis or endarteritis; and the other the not so common atrophic form of degeneration, in which there is apparent atrophy, beginning in the intima and extending to the media. This is the usual senile change, and just to the extent that it is presenile, do we find the symptoms resulting from chronic cerebral anemia; the confusion in mental effort, loss of memory and progressive muscular weakness, which disappears after a period of rest and improved metabolism, only to reappear on the resumption of active life.

I believe that there is, under certain conditions, an angioneurotic edema, involving small areas of the cortex, which gives rise to focal symptoms that disappear as suddenly as they come; also, that in the so-called uremic palsies there is a local ischemia followed by hypostasis; because, in all the cases that I have had an opportunity to observe these conditions existed in other organs or parts, and particularly in the kidneys.

Dr. C. Eugene Riggs, St. Paul: I find in all cases that the use of the manometer is a matter of much practical importance. I remember a case of arteriosclerosis which I saw about a year ago. The patient had had a slight hemorrhage evidently, recovered from it, but complained of a great deal of dizziness and vertigo and much general distress and the indefinite symptoms which arteriosclerotics describe. The blood pressure registered 275, and then the tubing of the manometer broke, so that I could not measure the pressure further. Treatment for the relief of pressure proved efficacious. The patient is living very comfortably, but of course is still arteriosclerotic. I have had a number of cases in which much benefit has been derived by the use of the well-known remedy which we are almost inclined to disregard because of our familiarity with it, calomel. Calomel has some influence on metabolism and probably thus affects arterial tension.

The clinical picture of arteriosclerosis is very confusing. There are undoubtedly many forms of pathologic manifestations included under this name. Whether or not arteriosclerosis is due to toxemia affecting the smaller vessels and the capillaries and thus increasing the tension and after a while causing the change in the vessels, is a matter of theory perhaps, but certain it is that in these cases if the patient is put to bed and rested, given calomel and put on a light diet, usually the blood pressure will come down, and the vertigo will be materially relieved; and it is a very common thing to find the patient going on for years without any material change. Dr. Clifford Allbutt speaks of a case which he observed for nineteen years in which there were various attacks of hyperpiesis which were relieved, after which the patient was comfortable.

Dr. Julius Grinker, Chicago: It is the cases which present focal symptoms which trouble us rather than the ones presenting general symptoms of arteriosclerosis. We are often confronted with these cases and are asked: "Is this a tumor, or is it cerebral arteriosclerosis?" Only recently I have been puzzled, as never before, by a case in which I was consulted as to whether or not there was a tumor of the cerebellum. The symptoms were very much like tumor symptoms, and resembled one of the cases which Dr. Jones so ably described—almost a sister case in every detail. It was very difficult to decide whether we had to deal with a tumor causing vertigo and incoordination of the cerebellar variety, a type of cerebellar arteriosclerosis. I believe that the only way we can learn something about these cases is by having as many postmortem reports as we are able to obtain, and then correlating the symptoms with the findings, because this subject needs revision and classification. The symptoms are rather vague; we are often unable to make a positive diagnosis, because cases presenting these symptoms may turn out to be neoplasm or internal hydrocephalus, or generalized arteriosclerosis or aneurismal dilatation of the arteries at the base of the brain.

Dr. Arthur S. Hamilton, Minneapolis: We have, of course, many cases of cerebral arteriosclerosis, but gross changes, such as were found in Dr. Jones' cases, and yet not including the well-known miliary aneurism, are, I think, not very common. There is a fair number of instances of aneurism of some one of the cerebral vessels on record, but they are rarely recognized until they are found postmortem. In most of the individuals a previous diagnosis of brain tumor has been made but, if no symptoms have been present during life, death, when it occurs, is usually assumed to be due to apoplexy from the ordinary causes. Very rarely, when the aneurism is large, an accurate diagnosis has been arrived at through the recognition of a bruit, but this is quite impossible when the aneurism is small. In at least one of Dr. Jones' patients the symptoms were evidently due, not to the size of the aneurism acting very much as a tumor, but to the disturbance of the circulation in important parts of the brain. Aneurism of the cerebellar vessels is particularly uncommon, probably because these vessels do not receive the full force of the blood pressure from the middle cerebrals, and because they are not often the seat of emboli which lodge and occasionally produce aneurisms behind them. Very recently I had an opportunity to examine the brain of a comparatively young woman, in whom, following the development of a very extensive vegetative endocarditis, an embolus had lodged in the right Sylvian artery and, directly below the point of lodgment, an aneurism, about the size of a pea, had developed.

Dr. W. A. Jones, Minneapolis: I want to emphasize the varying degrees of disease of the vessels other than the generally accepted arteriosclerosis. It seems to me that these cases emphasize the necessity of differentiating between arteriosclerosis and other diseases of the vessels. I appreciate the very great difficulty there is in making a positive diagnosis in any of these cases. The blood pressure in these cases is not great—in fact, it is often either normal or below normal. I do not know whether it would be helpful or not to take the blood pressure. It may be that that was improperly omitted. The venous return to which Dr. Tomlinson refers is a very natural sequence of the condition of the blood vessels that we found in these cases; and the obliteration or the simple subsidence of what was formerly a vessel would of necessity give rise to great changes in the cerebral circulation.

CEREBRAL INHIBITION WITH RELATION TO MOTOR FUNCTION.[*]

H. A. TOMLINSON, M.D.
Superintendent of the St. Peter State Hospital.
ST. PETER, MINN.

From time to time there have been cases under observation in the St. Peter State Hospital in which there was loss of capacity to coordinate muscular movements involved in prehension and locomotion. These cases could not be placed in any of the usual categories, because there was no evidence of organic disease in the general nervous system. In some of these cases the loss of control of muscular movement was so great that any voluntary action was impossible, while in others there was, apparently, complete palsy. We never have been able to determine the nature of the involvement of the central nervous system in these cases, because there has always been more or less complete recovery of functional capacity, and none of the cases has come to necropsy.

So long as these peculiar manifestations occurred in the ordinary course of brain degeneration, they were considered to be a part of the sequence to these degenerative changes, as I reported in two papers on the subject.[1] However, a number of cases have been under observation during the past three years, the course of which would indicate that extreme incoordination of voluntary movement, and even palsy, may result from simple cerebral inhibition.

The term inhibition is used here to define that function of the cerebrum which interferes between the afferent impulse and the direct motor response. During the progress of development, in the integration of the nervous system, this function has resided in the ganglia at the cephalic pole, and its development has been in a direct ratio with the growing complexity of the conditions in the environment of the animal; also *pari passu* with the multiplication of the specially organized areas for the reception and transmission of afferent impulses. Along with the increasing complexity of the organization has gone a corresponding amplification of the reflexes, and an increasing diversity of the functional elements of which they are composed; so that in the most multiform, there is a sequence, resulting from the correlation of a series of simple reflexes that are primarily antagonistic. Consequently, if anything occurs to interrupt this sequence, or disarrange the series, the antagonism of the individual elements becomes dominant. Therefore, along with the development of that part of the nervous system concerned with inhibition, there has gone the building up of another portion, the function of which is to maintain the sequence among the elements of the reflexes, and the proper relation in the series; that is, the function of coordination.

---

[*] Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

[1] Sensory and Sensory-Motor Disturbance Associated with Insanity, Jour. Nerv. and Mental Dis., October, 1892; The History of Three Cases of Peculiar Motor Manifestations in the Insane, Jour. Nerv. and Mental Dis., December, 1892.

In experimentation on the lower animals with regard to the conduction of sensation, and the resulting reflexes, it is first necessary to separate the cerebrum from the rest of the nervous system, in order to prevent the inhibition of the movement following the stimulus, or its modification; and to reduce the reflex to its simplest form. As we go up in the animal scale, the association of the reflex with the coordinate becomes so intimate, and the functions of the general nervous system so interdependent, that we can not separate them completely; until, in the highest forms, where this inhibitory control is greatest, this separation of the two is incompatible with the continuance of life. In other words, inhibition becomes so dominant that any sufficiently powerful shock to the general nervous system, and particularly one involving mutilation or separation of the spinal nervous system from its connection with the cerebrum, brings about an immediate and permanent cessation of activity. Even in those animals in which this isolation of the cerebrum is compatible with continued life, the necessary operation must be performed with the most delicate care, in order to prevent permanent inhibition of function. That is, the act of mutilation must be as free as possible from the elements of a stimulus. So far as I am aware, the converse of these observations has not been made, or at least not formulated with relation to incoordination and disintegration of motion in the most highly developed form of organization.

Any attempt at formulation of the process involved in the generation and coordination of the motor reactions involved in the highly complicated reflexes concerned with the adaptation of the individual to the varying conditions in the environment must necessarily be speculative, and, judging from recent discussions, we have lost a great deal of our supposed certainty as to the area of origin of the motor impulses for the most complicated reflexes. It has always seemed to me an inevitable deduction from the mode of development in the nervous system, that as soon as the organism has developed to the extent that impressions of different kinds, and various degrees of intensity, begin to arrive simultaneously in the central ganglia, the first and chief function of the elements in the central area must be to inhibit the efferent impulse, until the afferent impulses can be related and coordinated. As the nervous organization becomes more complicated, so as to be able to adapt the activities of the organism to the conditions in the environment, the number of elements that enter into the composition of a coordinate movement becomes not only very great, but these elements are also very diverse; with the result that the movement becomes a series of related antagonistic reflexes, in a regular sequence. If anything occurs to break up this series, or to interrupt the sequence, the movement is incomplete, abortive, or entirely arrested. This can easily be illustrated in the new-born child. There is no coordinate movement except that involved in the act of nursing, which is a combination of motor impulses of the same type as the scratch reflex described by Sherrington. If the child is placed in the position to nurse, and just as it takes hold of the nipple, the bottom of either foot is stimulated, the movement of nursing is arrested. Again, if the child is nursing, and the stimulus is applied, the movement of sucking is arrested, to be renewed as soon as the stimulus ceases; provided the application of the stimulus is intermittent. If the stimulation is continuous, the child lets go the nipple and begins to cry. With each inspiration the voluntary muscles are relaxed; while with expiration they are contracted. At the same time the force of the heart beat is increased and the peripheral vessels are dilated. Here are a host of apparently unrelated reflexes brought into action, most of them antagonistic, but following each other in a regular sequence. The different compound reflexes may be tested in turn, but if any two antagonistic reflexes are stimulated at the same time, inhibition always results, to be followed by the gradual domination of flexion.

These observations have taught me that the new-born child is as good a subject in which to study the reflexes as is the decerebrate dog, and for the same reason, that is, functionally it is decerebrate. We may make accurate observations under experimental conditions, using the clinical opportunities that come to us in our everyday work, without the aid of elaborate laboratory apparatus; and I wish to impress on you that our institutions for the insane are unworked mines of neurologic wealth.

The development of coordinated movement in the infant follows the combination of antagonistic simple reflexes, so that they shall be supplementary to each other; but at any time these compound reflexes may be disintegrated by overstimulation of the flexion or extension element; or the movement may be entirely inhibited by the stimulation of an indifferent area having another form of functional activity. As the functional capacity of the cerebrum develops, these inhibitions become more frequent and active; until the response to the afferent stimuli is completely coordinated, and there is so-called voluntary motion. Thereafter, combinations of primarily antagonistic reflexes become more and more numerous, as the conditions in the environment become more uniform, and familiar by repetition; so that highly complex reflexes exist, apparently free from cerebral inhibition. But should any given combination of conditions in the environment change, so as to vary the intensity and relation of the resulting afferent impulses, the given impulse is first inhibited, and then its elements are recombined to meet the changed conditions. This is illustrated constantly in the futility and confusion that result when an individual is called on suddenly to meet unusual and untoward conditions in the environment, or when, for reason, he has lost the capacity to relate and coordinate the afferent impulses coming from accustomed environment.

Unfortunately, the motor reactions and reflexes have not been studied in the same detail in the human organism that they have been in the lower orders of animal life; so that there is a hiatus in our knowledge of the order in which cerebral inhibition has developed. Besides, we are prone to forget that there is no standstill in the functional capacity of the cerebrum. New modes of activity are constantly being integrated; combinations and recombinations; adaptations and readaptations are constantly taking place; increasing in complexity, or disintegrating into simpler forms. It is important, too, to remember when considering the development of the cerebrospinal nervous system, that there is a difference between anatomic arrangement and functional capacity. While anatomically there has been comparative uniformity, and in histology likeness, functionally there has been constant variation; often reversion: and sometimes almost complete disintegration of most complex reflexes. These variations are well illustrated in the modifications in functional capacity of the different special senses, by the artificial conditions which have grown into the human environment; so that the functional capacity of all the special senses has become more uniform, and instead of vision, smell, or hearing being conspicuously dominant, they share comparatively equally with the other senses the task of adaptation to the conditions in the environment; and yet there is neither anatomic nor morphologic change in the elements of their cerebral centers. So, too, it is possible that without anatomic difference or morphologic unlikeness in the elements of the brain cortex, there may be relative incapacity in the development of functional potentiality in the cortical areas of the highest forms of cerebral functioning; resulting in temporary or permanent failure under stress of the capacity for coordination and direction. Therefore, there may be disintegration of function and disassociation of the elements of complex motor activities, without lesion or morphologic change in the histologic elements of the cortex of the brain.

Sherrington[2] has shown in detail how the reflexes are built up, but he first eliminates the inhibitory function of the cerebrum, and he does not show how these reflexes are combined, controlled and the efferent impulses directed in so-called conscious effort by the cerebrum; although, in the last chapter of his book, he sums up the relation of the cerebrum to motor activity from the standpoint of our present knowledge.

From observations of new-born children I have learned that, in order to construct a compound reflex, it is necessary that all the afferent impulses should be received in their proper order and related in their habitual sequence. When this order and sequence are interrupted or incomplete, the efferent impulses are inhibited, and then the reflex is modified. From observations among the insane, it has been found that the progress of degeneration in dementia brings about a similar state; so that as the capacity for relation, coordination and direction are lost, inhibition becomes dominant. Then, in the presence of physical deterioration, or some cause of vasomotor disturbance, there are various degrees of inhibition, ranging from incoordination to palsy, usually in the functions of prehension and locomotion and next in the acts of articulation and deglutition.

The following case histories illustrate this contention:

Patient.—L. D., woman, born in Minnesota, 27 years old, a farmer's daughter.

Family History.—The paternal grandmother is still living; the other grandparents died in old age after healthy lives. The parents are still living and in good health. There are six children in the family, and all of them in good health except the patient. The parents were in good physical condition at the time of the conception of this child; she was healthy as a baby and during her childhood she began to menstruate at 14 years of age; the function was established without disturbance, and she was healthy until her nineteenth year, when she had "spasms" for two days, and since that time is said to have had "epilepsy."

Personal History.—Ten months before coming to the hospital it was noticed that when alone she would talk incoherently to herself. After this time she became suspicious, and when interfered with, violent; also noisy and profane. She believed that her family wanted to harm her, developed furtive suspicion, was sullen and obstinate, would attack any one who came near her, and destroyed her clothing and the furniture.

Examination.—She was admitted April 8, 1907. She was poorly nourished, the skin was dry and harsh, the flesh flabby. She weighed 103 pounds, although tall and large boned. The chest was depressed above the clavicles; the circumference 75 cm., expansion 4 cm. Resonance was impaired over the apices, sibilant râles were present in the interscapular region, and moist râles in the subscapular region. The heart was slightly enlarged, the sounds were clear and distinct; the aortic second sound was accentuated. There was no atheroma apparent. The abdomen was flattened, its walls thin. The tongue was heavily coated, the appetite poor, digestion impaired, and she was constipated. The labia minora were hypertrophied, the hymen lacerated, the uterus small and anteverted. Apparently the ovaries and tubes were healthy.

Urine: The urine indicated chronic renal congestion, and functional inadequacy of the kidneys. Indican was much increased, there was a small amount of albumin, deutero-albumose, acetone and diacetic acid, as well as numerous uric acid crystals.

Muscles and Reflexes: The muscles of the face were under poor control, but the movements of the eyes were coordinate, and the tongue was protruded readily in the median line. The pupils were 5 mm. in diameter, equal, and reacted to light and accommodation. The hand grasp was 48 in the right and 38 in the left, and there was no paresis. There was slight tremor about the mouth, intention tremor in the tongue, and slight rest tremor in the arms. The superficial reflexes were present; the knee jerks were exaggerated, and increased on reinforcement. There was no ankle clonus. Coordination was poor in both arms and legs. On account of the dulness and suspicion, common sensation and the special senses could not be tested.

Mental State and Motor Disturbance: She was untidy and indifferent; stooped, walked unsteadily, hopped, and dragged her feet. The expression was vacant, she did not respond to questions except by yes or no, but whispered incoherently to herself. She was alternately exalted and depressed; restless, irritable, and there was auditory and visual hallucination. When asked to do a thing she would twist herself about spasmodically, say "I can't," make a great many futile efforts and purposeless movements, and finally accomplish the coordinated movement. When alone she would grimace and gesticulate, and her body and lower limbs twitched. In trying to sit down, she would look about her, grin, grasp the chair, put her left knee on it, and then drop down with the left leg doubled under. She had a shuffling, unsteady gait, and was apparently in constant fear of falling. When food was given her she would make no effort to feed herself until after some of the food had been put in her mouth, when she would go ahead and eat a hearty meal. She could not take off or put on her clothing alone; while in getting out of or into bed, she would make a number of ineffectual efforts, with gesture and contortion; finally rolling and throwing herself on to her feet, or into the bed.

Course of Disease.—During the first month she was in the hospital she was in worse condition than when admitted; became disturbed, restless, noisy, and at times filthy. The incoordination was more extreme; so that efforts toward prehension and locomotion were almost entirely futile. In her efforts to go from place to place, she would twist her shoulders, throw the elbows out from the body, make a few uncertain dragging movements with the feet, lean forward, then take several rapid steps backward; and finally with a propulsive impulse she would start forward *on a run; finally* settling into a walk in the direction she wanted to go. When asked to shake hands, she would slowly extend the arm in an uncertain movement, suddenly withdraw it, go through a number of gyrating movements of the body and arms, then after several futile efforts propulsively extend the arm and shake hands. The nurses frequently helped her to walk by moving her feet forward alternately for several steps, until she could coordinate the movement and walk without assistance. She gradually improved physically, but remained *suspicious, irritable, obstinate*; kept by herself, was usually sullen, and sometimes noisy, profane and disposed to be violent. Later the motor incoordination grew less, she could move about without much difficulty, became brighter and more cheerful, and began to occupy herself in various ways.

---

[2] The Integrative Action of the Nervous System.

In December she weighed 140 pounds, was in good physical condition and much improved mentally. Her parents took her home and when last heard from there was no incoordination, and she was engaged in the usual activities of a farm household.

Patient.—J. M., man, aged 21, born in Minnesota.

Family History.—The father, a healthy, vigorous man, was, when a young man, a lumberman. The mother is, and always has been, neurotic. No definite information could be obtained concerning the grandparents.

Personal History.—The patient was born at full time, the mother was able to nurse him, and he had no serious illness during childhood. He was not so bright as his brothers and sisters, was obstinate, and not amenable to discipline. Punishment made him sullen, and neither stimulated nor deterred him. While apparently fond of his family, he never expressed any feeling for them, and did not actively share the joys and griefs of his brothers and sisters. He did not associate with other children, but stayed either with his parents about the house, or in the company of other adults. He was very selfish, inconsiderate of his parents, and even as a child responded to bribes only. Punishment did not affect him. From the time of the period of second dentition he would, when alone, stand staring into space, apparently oblivious of his surroundings. Often he would stop in the middle of the street and look about him apparently at nothing for half an hour at a time; and he would stop outside of the house, regardless of the weather, for an indefinite period, unless he was called in. He was always in good physical condition, ate and slept well, and grew as rapidly as the other children. He spoke rapidly and explosively, did not stutter, but would leave out words, or repeat himself frequently. He did not take much exercise, but read a great deal, apparently only to occupy his time. He was naturally furtive and deceitful; disinclined to work; but *ingenious in hiding his derelictions. He had no sense of* responsibility or moral obligation, and although he learned easily, he would not go to school regularly, and did no work after he was 20 years old, but hung about dance halls and cheap theaters; he came in late at night and was never willing to tell even his brother of his movements. So far as could be found out he neither drank nor frequented houses of prostitution, but in the spring of 1905, when he was 21 years old, he wanted to marry a street walker.

Development of Incoordination.—In the autumn of 1905 his peculiarities became more marked, he became ugly and disposed to be violent toward the members of the family. In February, 1906, he came home late one night in a cab, said that he saw a man drop dead, and was so frightened that he was afraid to come home alone. After getting home he was afraid to stay alone. This fear persisted, he talked more rapidly, repeated oftener, and was sometimes incoherent. At this time it was also noted that it took him a long time to eat his food; also to dress and undress. He walked very slowly, was careful of his steps, and examined anxiously the space in front of him before taking a step. He would not go anywhere out of the house unless accompanied by his parents. He was placed in a hospital, soon became confused; later stupid; passed his urine and feces in bed; required constant personal care, and seldom spoke. He took little food, became emaciated, and either could not or would not use his arms or legs in prehension or locomotion. His parents, thinking he was going to die, took him home; but soon after getting him home he began to improve physically, looked after his own secretions, and was apparently not so timid, although he was very deliberate in his movements. It was soon after this time that I saw the young man in consultation.

Examination.—The patient presented the appearance and manner of a boy of 14 years of age, and there was practically no hair on his face. He was awkward, self-conscious; with extreme facial mobility, general restlessness and emotional exaggeration. In attempting to shake hands he struggled vainly for some time to bend the elbow and raise the hand; moving the other arm and the body, but he was unable to raise the arm or extend the hand. Finally, after a number of futile efforts, he suddenly put out his hand and shook hands. He also had considerable difficulty in letting go the grasp of the hand; going through a number of gyrations with the arms and contortions of the body before he could let go. He spoke rapidly, repeated almost every word, was apparently in con*stant motion; yet never succeeded in doing anything until after* continued effort. When he undertook to pick up a knife, spoon or fork, the same series of unavailing efforts were made; and after the object was taken into his hand, another series of efforts was made before he could begin to make use of the object. After he was started, however, he could continue any combination of movements indefinitely, but he had the same difficulty in stopping that he had in starting. It took him sometimes fifteen minutes to start to move, but having started, *he could move in a straight line indefinitely, but at a turn, or* in stepping from one level to another, the same struggle took place. If asked to pick up a pencil and write, he would make a whole series of movements before he succeeded in grasping the pen. The pen in his fingers, there followed a spasm of the muscles of the hand, lasting about half a minute. Then he would start to write, getting along without difficulty, and writing fluently, either spontaneously or from dictation. It was as much of a task, however, to let go of the pencil as it *had been to pick it up.* In walking, if he saw some one coming toward him, or if, in crossing the street he saw a team coming toward him, he became rigid and could not move again until after considerable effort. Every thing he undertook was a repetition of the series of inhibitions and incoordinate movements here described. Nothing wrong could be discovered in the motor or sensory functions of the nervous system, and he was in good physical health, had a good appetite and slept well, and yet every voluntary effort was inhibited by an antagonistic reflex.

Treatment.—The treatment, aside from the employment of a tactful and strong-willed nurse, was the systematic retraining in coordinate movement of all of the muscle groups. In the course of three months the young man was much better, and he has slowly improved since that time, so that he can now go anywhere alone and care for himself. The mental enfeeblement is, of course, permanent; he is still very emotional, speaks very rapidly, and has practically no self-control.

Patient.—A. T. L., woman, born in England; single, aged 17 at the time of admission. The father, a farmer, is living; the mother died in childbirth. No other history of the family could be obtained.

History.—The patient, *one of twins*, was born after a difficult labor. The other child was born dead, and the mother died soon afterward. When nine months old the patint had convulsions and "severe fever." Following the convulsions she had a left hemiplegia, from which she gradually recovered. She began to menstruate at 14 years of age, and soon afterward developed epilepsy, the convulsions being nocturnal at first. She became dull, irritable, obstinate, and at times violent.

Examination.—When admitted to the hospital February, 1907, she was disturbed, noisy and violent. She was well-nourished, the flesh firm and vitality good. There was no evidence of disease in the chest or abdomen. There was some indigestion and she was constipated. The urine indicated renal inadequacy and there was some albumin and casts.

Muscles and Reflexes: The face was asymmetrical. The tongue was protruded readily, but deviated to the right. She stuttered. The pupils were dilated and equal. There was some twitching of the eyelids, slight intention tremor in the limbs; the knee jerk was exaggerated and increased on reinforcement; coordination was fair and there was no clonus. She was too dull and irritable to make subjective tests.

Course of Disease.—During the time of her residence in the hospital her history has been the usual one of a demented epileptic. Explosive outbreaks followed by periods of dulness, and occasional intervals of comparative brightness. In the spring of 1906 it was noticed that she was very awkward and was gradually losing the power of motion in the lower limbs, so that she stumbled and fell frequently. For some time previously she had been having an unusual number of convulsions, was irritable, obstinate, and frequently explosively violent. The weakness in the lower limbs increased, the paresis being apparently more marked in the extensors, until in June there was complete paraplegia.

Description of Paralysis: The paralysis was spastic and most marked on the left side. Each group of muscles, however, responded to stimulation and there was no reaction of degeneration. The paralysis slowly disappeared, but the incoordination remained for about a year. At present she is awkward and has a rolling gait. During the time she was in bed numerous tests were made of the coordination in the arms, with the result that movements of prehension were at first difficult. and at the time the paraplegia was most complete, impossible. Even now considerable effort is necessary for her to take anything in her hands. When she is dull the incoordination is still marked in both upper and lower extremities, but during her brighter intervals, she has very little difficulty in either prehension or locomotion. However, if she becomes disturbed for any reason, she begins to stagger, and if not supported will fall to the floor.

These three cases were chosen because they formed a sequence, showing the varying degrees in the development of inhibition, according to the extent of the primary defect in the nervous organization, and the advance of the process of dementia. I have seen these inhibitions in the terminal stages of general paresis, and they, for obvious reasons, are frequently present in hysteria. Indeed, in hysteria, the palsies and contractures are graphic illustrations of disintegrated compound reflexes, primarily due to inhibition.

There are, however, in every-day experience, frequent examples of inhibition, resulting from fear or other emotion; and it is to be noted that these examples are conspicuous just in proportion to the instability of the individual in whom they are manifested.

The pathology of this condition is obscure, and it has no morbid histology, so far as the brain cell is concerned. There is no means by which we may become familiar with the process involved, because even in those cases in which the incoordination or palsy persists the secondary degenerative changes obscure any primary alteration that might have been present. However, the evidence furnished by current knowledge of the physiology of the brain shows fairly conclusively that the function of inhibition is most highly developed in the cortex of the middle portion of the frontal lobes anterior to the precentral fissure. That is, the areas connected with the lower, middle, and upper portions of the anterior central convolution. It would seem that these areas are grouped together functionally with relation to motion, just as the inferior and superior parietal lobules are grouped with the subdivisions of the ascending parietal convolution with relation to sensation. As I have stated in another connection,[4] atrophy in the cortex, in the progress of degeneration, always begins in the convolutions of the operculum, and is usually most marked over the posterior portion of the second and third frontal convolutions on the left side, in right-handed persons. Again, in the defective, this is the part of the brain that is least well developed. I have found, also, that it is in this area, in the blood vessels distributed to the cortex, that atheroma, with white streaks along the vessels, appears first. Besides, the veins in the frontal area are always the most tortuous and distended, and their entrance into the sinus most narrowed by the piadural adhesions along the median fissure; so that there is not only interference with nutrition and elimination, but a mechanical cause for atrophy in the accumulation of fluid in the arachnoid space.

We have recently had the opportunity to see these conditions in two cases of cranial vivisection, in one case while searching for the assumed cause of mental degeneration in an old cranial injury. Although the site of the injury was over the left superior parietal lobule, the atrophy was about the insula. The arachnoid space over the frontal lobes was distended with fluid, and there were white streaks along the vessels. The brain did not pulsate. There was no evidence of change at the site of the injury, except some thickening of the outer table of the skull. This patient, a man, was confused, irritable, often denuded himself, and wanted to "get away from here." That is, there was reversion to the animal tendency to seclusion.

The other case was one of epileptiform convulsions, with confusion and explosive outbreaks of violence, procursive, and the sequence to visual and auditory hallucination. The convulsions followed a severe attack of typhoid fever, during which delirium had been severe, and the convulsions had continued for twelve years. They had been infrequent at first; then occurred in groups at irregular intervals. These intervals became shorter, and about a year before coming to the hospital the patient was noted, when alone, to laugh and talk incoherently to himself. About three months before he was admitted the convulsions became rather frequent and the mental disturbance active. The convulsions, although usually general, began in the muscles of the right side of the face. After the convulsion he was very much confused for several days. During one of these periods of confusion, in a procursive explosion, he jumped out of the window, ran some distance from home, and hid in an old barn. It was after this escapade that he was committed to the hospital.

When the cranial flap was turned down on the left side, an area of thickening in the dura over the operculum was found, and underneath a retention cyst in the pia. The brain bulged into the opening and the convolutions were flattened. The arachnoid space over the frontal lobes was distended with fluid, there were white streaks along the vessels, and the veins were distended and tortuous. The brain did not pulsate, until after pushing a trocar into the lateral ventricle and draining out considerable fluid. In this case there was not much atrophy, but the convolutions were flattened by the intraventricular pressure—the periods of confusion corresponding with the accumulation of fluid resulting from the hypostasis following the convulsion.

In neither of these cases was there any incoordination, and both patients were men in middle life. They are referred to here to show the condition of the brain in acute mental disturbance in the course of chronic degenerative change, and because they suggest the probability that in all cases of confusion and stupor there is pressure from an increased amount of fluid in the lateral ventricles; while in the cases that are disturbed the fluid is probably over the convexity.

---

[4] The Motor Degenerative Sequence in Dementia, THE JOURNAL A. M. A., Oct. 27, 1906.

In my experience inhibition and incoordination occur only in those cases in which the degeneration is primary and begins during adolescence, that is, when degeneration begins before development is complete. In these individuals the higher functions of the brain are necessarily imperfectly developed, with the consequence that coordination and direction are not completely organized. Therefore, anything that lowers vitality may put these functions in abeyance, and leave inhibition dominant, just as in the normal individual unusual and untoward conditions may operate to produce the same result in the undeveloped and inexperienced.

IMPERFORATION OF THE LACHRYMONASAL DUCT IN THE NEW-BORN, AND ITS CLINICAL MANIFESTATIONS.*

WILLIAM ZENTMAYER, M.D.
PHILADELPHIA.

The common clinical manifestation of obstruction to the lachrymonasal duct in the new-born has been usually described under the term "congenital dacryocystitis," a very unsatisfactory one as a cystitis is not usually present, and when present is of secondary origin. Jackson[1] has recently written on the subject under the title of "Delayed Development of the Lachrymal-nasal Duct," an entirely proper term, in a restricted sense, but not intended to cover all the conditions which may give rise to the symptoms of so-called congenital dacryocystitis.

Until the appearance of the paper of Peters[2] but little consideration had been given this interesting and important subject and it is only within the past decade that frequent references to it are to be found in literature. Few of these are by American authors, and these mostly within the past three or four years. Historically, it is of interest to note that in the first edition of the Graefe-Sämisch Handbuch, Schirmer states that until Critchett published his cases, infants at the breast were considered exempt from dacryocystitis (Kipp). Kipp[3] says his statistics show that 10 per cent. of all cases of dacryocystitis, among which were several cases of phlegmon of the sac, occurred in children, under 1 year of age. But it was not until the appearance of the paper of Peters that the subject was broadly considered, and a causal relationship established between the clinical phenomena and the developmental peculiarities of the lachrymal passages. The investigations of Rochon-Duvigneaud,[4] Vlacovitch,[5] Stanculeanu,[6] and others, established from anatomic research the existence of structural abnormalities as well as delayed development as causes.

As it is the author's purpose to present principally the clinical side of the subject and to emphasize the method of treatment which he considers best meets the indications, no extended account of the embryology of the tear passages will be given.

EMBRYOLOGY.

The accepted view of the development of the lachrymonasal canal is that in the young fetus there exists a groove between the external nasal, the frontonasal and the maxillary processes, extending from the eye to the outer border of the nasal opening. The nasal duct arises as a thickening of the epidermis along the line of the lachrymonasal groove. This forms a solid ridge, which separates, except at each end, and forms a solid cord (Ryder). This cord becomes converted into a canal by a separation of the epithelial cells. The resulting débris, up until the seventh month or later, fills the canal with a gelatinous mass.

ETIOLOGY.

The possible causes of the condition manifesting itself as a discharge from the puncti, a distention of the sac or an abscess in the new-born are sixfold: (1) Delayed separation and necrosis of the epithelial cells forming the cord from which the canal is formed. (2) Retention of the separated cells through imperforation of the septum between the lachrymonasal duct and the nasal chamber. (3) Through obstruction due to annular folds of the mucous membrane which may form at any point within the duct, Huschke's and Hasner's valves. (4) Faulty development of the cartilages (D. Gunn[7]). (5) Partial occlusion by pressure of inferior turbinate. (6) Stenosis from pressure exerted on the bones of the face during instrumental labor. (The last group is a suppositional one, suggested by Peters' observation that in one of his cases there were marks of the forceps over the nose on the side corresponding to the discharge from the punctum.)

The majority of the cases doubtless fall under the second group, as here the cause is one for which the anatomic possibility exists in every fetus. It would seem probable that this affection might be found proportionately more frequently in the prematurely born as the septum is usually present until shortly before birth, but Stanculeanu[6] found the condition of so-called congenital dacryocystitis present only four times in twenty embryos at the seventh month, the period previous to which, according to this writer, the lachrymonasal duct is never patulous. He believes that this observation overthrows the classical theory as to the pathogenesis of this condition. He was, however, unable to demonstrate an infection to explain the cases that he did observe; but Rochon-Duvigneaud[4] holds that to produce this condition there must be an exaggerated proliferation of the epithelium of the canal. Morax believes that infection first takes place after the birth of the child, and therefore considers the term "congenital dacryocystitis" incorrect.

COMPLICATIONS.

A distention forming a diverticulum at the lower part of the sac is an associated condition, the presence of which, often suspected from the clinical phenomena (Vossius,[8] D. Gunn,[7] Addario) has now been demonstrated in section by more than one investigator (Rochon-Duvigneaud,[4] Vossius[8]). This abnormality may be due to a faulty development, or as is more often the case, by distention of the duct by retained epithelial débris and mucous secretion. The latter, as pointed out by Bochdalek, forming a consistent mass, may, in itself, obstruct the lumen of the canal and hinder egress to the nose. Mayou[9] has shown that throughout development the lower end of the lachrymal duct is extremely small and remains so at birth, being partially occluded by pressure of the inferior turbinate bone. That a catarrhal or even purulent conjunctivitis may be excited by the contents of the lachrymal sac was demonstrated by Ollendorff's[10] cases and by the cases of Gunn,[7] where the inflammation of this membrane at once subsided when the duct was made patulous.

Lachrymal abscess figures as a sequel to atresia of the duct. D. Gunn[7] has seen five cases of this nature in infants ranging in age from nine days to six months, in which the method and result of treatment left no doubt as to the origin. Mayou[9] has treated eight cases occurring in the first few weeks of life the result of secondary infection from ophthalmia neonatorum or from organisms which may gain entrance to the lachrymal sac. Van Duyse,[11] Selenkowsky[12] and others record like cases.

SYMPTOMATOLOGY.

It needs but a brief chapter wherein to describe the symptoms by which congenital obstruction of the lachrymonasal duct presents itself. Immediately, or within a few days after the birth of the child, a small amount of white or yellowish-white discharge is noticeable at the inner angle of the eye. The conjunctiva is usually normal, or but slightly injected. There may or may not be fulness over the sac. Pressure applied over this region may cause a gelatinous white fluid to exude from the punctum. If there has been distention, the pressure may cause the fulness to disappear, accompanied or not by a discharge from the puncti or from the nose. In some instances there is associated a catarrhal conjunctivitis, which occasionally takes on a purulent type.

If proper treatment is withheld, under the influence of winking, the conjunctival secretions penetrate and infect the gelatinous contents of the sac and excite an inflammation which may continue as a subacute condition or kindle an acute process.

The affection is very rarely bilateral.

BACTERIOLOGY.

As might well be expected from the circumstances, a great variety of micro-organisms have been found in the secretion. Merconti[13] saw a bacillus resembling the coli communis. The gonococcus of Neisser was found by Antonelli[14] and Mayou,[9] the pneumococcus by Hirsch[15] and the *Staphylococcus pyogenes aureus* by Selenkowsky,[12] and the Morax-Axenfeld bacillus by Mayou. Ball[16] states that the xerosis bacillus, the pneumobacillus and the *Bacillus fetidus ozena* have all been found.

PROGNOSIS.

This is undoubtedly good in a great majority of instances, as it has been shown that in those cases where there is either an incompletion of the cleaning up process or an imperforation of the thin diaphragm at the inferior meatus, Nature, in time, corrects the trouble; but at any stage in the process, infection of the contents of the canal may determine an inflammatory process, leading to abscess formation, if immediate drainage into the nose is not secured. An injury to the cornea, or a marasmic ulceration of the cornea, might endanger the safety of the eye, as evidenced by Selenkowsky's case of phlegmon of the tear sac in the new-born in which the *S. pyogenes aureus,* of a highly virulent type, was present in large numbers. Purulent conjunctivitis may be set up by infection.

Considering that one careful observer has found that 25 per cent. of his cases of dacryocystitis occurred before the tenth year, it is likely that chronic dacryocystitis in the child may be looked on as a possible sequel to the congenital obstruction.

DIAGNOSIS.

To those familiar with the occurrence of the affection, its diagnosis presents no difficulties; but to the general practitioner, alert to possible occurrence of gonococcal conjunctivitis, the presence of a white secretion in the eye, just after birth, is a disturbing symptom. The absence of inflammatory phenomena, with puffiness of the lids, the benignity of the course, the usual monolateral development, and the scantiness of the discharge, should ease his mind, and if it does not, a microscopic examination of the discharge would.

Terson[17] has seen in a prematurely born, but well developed female child, a hemispherical fluctuating tumor, of about the size of a hazelnut, overlying the right lachrymal sac. It was absolutely irreducible and unattached to the skin. The nature of the cyst was problematic. According to Terson, the possibility of such a tumor being a meningocele, an encephalocele, or of the nature of a true prelachrymal serous or fatty cyst, must be borne in mind. The elder Terson removed from an adult the anterior portion of a prelachrymal cyst which was entirely independent of the healthy lachrymal passages, yet proved, histologically, to be made up of tissue normal to the lachrymal sac.

According to Terson the differential diagnosis between prelachrymal cysts of various kinds, and so-called congenital dacryocystitis is extremely difficult. In certain cases it must rest entirely on the irreducibility of the tumor.

TREATMENT.

Varied opinions are held concerning the proper management of these cases. Some surgeons (Weeks,[18] Jackson,[1] Peters,[2] Panas, Terson,[17] Valude[19] and others), believing that as the condition is one which, in the vast majority of instances, will correct itself in time, presumably without exciting any secondary disturbance, advise a simple collyrium, the use of solutions of silver, of pressure, and massage, until Nature has asserted herself, or for several months before employing operative procedures, Ollendorff,[10] Koster,[20] Cutler,[21] Rochon-Duvigneaud,[4] Parsons,[22] Bochdalek, Mayou and others[23] employ probing or syringing. Peters has, at times, used probes. Parsons, who holds a decided opinion as to the injurious effect of probing in the adult, apparently makes an exception in *treating this affection in the* young, as he states that a single probing usually brings degenerative change, and because they suggest the probability that in all cases of confusion and stupor there is pressure from an increased amount of fluid in the lateral ventricles; while in the cases that are disturbed the fluid is probably over the convexity.

In my experience inhibition and incoordination occur only in those cases in which the degeneration is primary and begins during adolescence, that is, when degeneration begins before development is complete. In these individuals the higher functions of the brain are necessarily imperfectly developed, with the consequence that coordination and direction are not completely organized. Therefore, anything that lowers vitality may put these functions in abeyance, and leave inhibition dominant, just as in the normal individual unusual and untoward conditions may operate to produce the same result in the undeveloped and inexperienced.

IMPERFORATION OF THE LACHRYMONASAL DUCT IN THE NEW-BORN, AND ITS CLINICAL MANIFESTATIONS.*

WILLIAM ZENTMAYER, M.D.
PHILADELPHIA.

The common clinical manifestation of obstruction to the lachrymonasal duct in the new-born has been usually described under the term "congenital dacryocystitis," a very unsatisfactory one as a cystitis is not usually present, and when present is of secondary origin. Jackson[1] has recently written on the subject under the title of "Delayed Development of the Lachrymal-nasal Duct." an entirely proper term, in a restricted sense, but not intended to cover all the conditions which may give rise to the symptoms of so-called congenital dacryocystitis.

Until the appearance of the paper of Peters[2] but little consideration had been given this interesting and important subject and it is only within the past decade that frequent references to it are to be found in literature. Few of these are by American authors, and these mostly within the past three or four years. Historically, it is of interest to note that in the first edition of the Graefe-Sämisch Handbuch, Schirmer states that until Critchett published his cases, infants at the breast were considered exempt from dacryocystitis (Kipp). Kipp[3] says his statistics show that 10 per cent. of all cases of dacryocystitis, among which were several cases of phlegmon of the sac, occurred in children, under 1 year of age. But it was not until the appearance of the paper of Peters that the subject was broadly considered, and a causal relationship established between the clinical phenomena and the developmental peculiarities of the lachrymal passages. The investigations of Rochon-Duvigneaud,[4] Vlacovitch,[5] Stanculeanu,[6] and others, established from anatomic research the existence of structural abnormalities as well as delayed development as causes.

As it is the author's purpose to present principally the clinical side of the subject and to emphasize the method of treatment which he considers best meets the indications, no extended account of the embryology of the tear passages will be given.

EMBRYOLOGY.

The accepted view of the development of the lachrymonasal canal is that in the young fetus there exists a groove between the external nasal, the frontonasal and the maxillary processes, extending from the eye to the outer border of the nasal opening. The nasal duct arises as a thickening of the epidermis along the line of the lachrymonasal groove. This forms a solid ridge, which separates, except at each end, and forms a solid cord (Ryder). This cord becomes converted into a canal by a separation of the epithelial cells. The resulting débris, up until the seventh month or later, fills the canal with a gelatinous mass.

ETIOLOGY.

The possible causes of the condition manifesting itself as a discharge from the puncti, a distention of the sac or an abscess in the new-born are *sixfold*: (1) Delayed separation and necrosis of the epithelial cells forming the cord from which the canal is formed. (2) Retention of the separated cells through imperforation of the septum between the lachrymonasal duct and the nasal chamber. (3) Through obstruction due to annular folds of the mucous membrane which may form at any point within the duct, Huschke's and Hasner's valves. (4) Faulty development of the cartilages (D. Gunn[7]). (5) Partial occlusion by pressure of inferior turbinate. (6) Stenosis from pressure exerted on the bones of the face during instrumental labor. (The last group is a suppositional one, suggested by Peters' observation that in one of his cases there were marks of the forceps over the nose on the side corresponding to the discharge from the punctum.)

The majority of the cases doubtless fall under the second group, as here the cause is one for which the anatomic possibility exists in every fetus. It would seem probable that this affection might be found proportionately more frequently in the prematurely born as the septum is usually present until shortly before birth, but Stanculeanu[6] found the condition of so-called congenital dacryocystitis present only four times in twenty embryos at the seventh month, the period previous to which, according to this writer, the lachrymonasal duct is never patulous. He believes that this observation overthrows the classical theory as to the pathogenesis of this condition. He was, however, unable to demonstrate an infection to explain the cases that he did observe; but Rochon-Duvigneaud[4] holds that to produce this condition there must be an exaggerated proliferation of the epithelium of the canal. Morax believes that infection first takes place after the birth of the child, and therefore considers the term "congenital dacryocystitis" incorrect.

COMPLICATIONS.

A distention forming a diverticulum at the lower part of the sac is an associated condition, the presence of which, often suspected from the clinical phenomena (Vossius,[8] D. Gunn,[7] Addario) has now been demonstrated in section by more than one investigator (Rochon-Duvigneaud,[4] Vossius[8]). This abnormality may be due to a faulty development, or as is more often the case, by distention of the duct by retained epithelial débris and mucous secretion. The latter, as pointed out by Bochdalek, forming a consistent mass, may, in itself, obstruct the lumen of the canal and hinder egress to the nose. Mayou[9] has shown that throughout development the lower end of the lachrymal duct is extremely small and remains so at birth, being partially occluded by pressure of the inferior turbinate bone. That a catarrhal or even purulent conjunctivitis may be excited by the contents of the lachrymal sac was demonstrated by Ollendorff's[10] cases and by the cases of Gunn,[7] where the inflammation of this membrane at once subsided when the duct was made patulous.

Lachrymal abscess figures as a sequel to atresia of the duct. D. Gunn[7] has seen five cases of this nature in infants ranging in age from nine days to six months, in which the method and result of treatment left no doubt as to the origin. Mayou[9] has treated eight cases occurring in the first few weeks of life the result of secondary infection from ophthalmia neonatorum or from organisms which may gain entrance to the lachrymal sac. Van Duyse,[11] Selenkowsky[12] and others record like cases.

SYMPTOMATOLOGY.

It needs but a brief chapter wherein to describe the symptoms by which congenital obstruction of the lachrymonasal duct presents itself. Immediately, or within a few days after the birth of the child, a small amount of white or yellowish-white discharge is noticeable at the inner angle of the eye. The conjunctiva is usually normal, or but slightly injected. There may or may not be fulness over the sac. Pressure applied over this region may cause a gelatinous white fluid to exude from the punctum. If there has been distention, the pressure may cause the fulness to disappear, accompanied or not by a discharge from the puncti or from the nose. In some instances there is associated a catarrhal conjunctivitis, which occasionally takes on a purulent type.

If proper treatment is withheld, under the influence of winking, the conjunctival secretions penetrate and infect the gelatinous contents of the sac and excite an inflammation which may continue as a subacute condition or kindle an acute process.

The affection is very rarely bilateral.

BACTERIOLOGY.

As might well be expected from the circumstances, a great variety of micro-organisms have been found in the secretion. Merconti[13] saw a bacillus resembling the coli communis. The gonococcus of Neisser was found by Antonelli[14] and Mayou,[9] the pneumococcus by Hirsch[15] and the *Staphylococcus pyogenes aureus* by Selenkowsky,[12] and the Morax-Axenfeld bacillus by Mayou. Ball[16] states that the xerosis bacillus, the pneumobacillus and the *Bacillus fetidus ozena* have all been found.

PROGNOSIS.

This is undoubtedly good in a great majority of instances, as it has been shown that in those cases where there is either an incompletion of the cleaning up process or an imperforation of the thin diaphragm at the inferior meatus, Nature, in time, corrects the trouble; but at any stage in the process, infection of the contents of the canal may determine an inflammatory process, leading to abscess formation, if immediate drainage into the nose is not secured. An injury to the cornea, or a marasmic ulceration of the cornea, might endanger the safety of the eye, as evidenced by Selenkowsky's case of phlegmon of the tear sac in the new-born in which the *S. pyogenes aureus*, of a highly virulent type, was present in large numbers. Purulent conjunctivitis may be set up by infection.

Considering that one careful observer has found that 25 per cent. of his cases of dacryocystitis occurred before the tenth year, it is likely that chronic dacryocystitis in the child may be looked on as a possible sequel to the congenital obstruction.

DIAGNOSIS.

To those familiar with the occurrence of the affection, its diagnosis presents no difficulties; but to the general practitioner, alert to possible occurrence of gonococcal conjunctivitis, the presence of a white secretion in the eye, just after birth, is a disturbing symptom. The absence of inflammatory phenomena, with puffiness of the lids, the benignity of the course, the usual monolateral development, and the scantiness of the discharge, should ease his mind, and if it does not, a microscopic examination of the discharge would.

Terson[17] has seen in a prematurely born, but well developed female child, a hemispherical fluctuating tumor, of about the size of a hazelnut, overlying the right lachrymal sac. It was absolutely irreducible and unattached to the skin. The nature of the cyst was problematic. According to Terson, the possibility of such a tumor being a meningocele, an encephalocele, or of the nature of a true prelachrymal serous or fatty cyst, must be borne in mind. The elder Terson removed from an adult the anterior portion of a prelachrymal cyst which was entirely independent of the healthy lachrymal passages, yet proved, histologically, to be made up of tissue normal to the lachrymal sac.

According to Terson the differential diagnosis between prelachrymal cysts of various kinds, and so-called congenital dacryocystitis is extremely difficult. In certain cases it must rest entirely on the irreducibility of the tumor.

TREATMENT.

Varied opinions are held concerning the proper management of these cases. Some surgeons (Weeks,[18] Jackson,[1] Peters,[2] Panas, Terson,[17] Valude[19] and others), believing that as the condition is one which, in the vast majority of instances, will correct itself in time, presumably without exciting any secondary disturbance, advise a simple collyrium, the use of solutions of silver, of pressure, and massage, until Nature has asserted herself, or for several months before employing operative procedures, Ollendorff,[10] Koster,[20] Cutler,[21] Rochon-Duvigneaud,[4] Parsons,[22] Bochdalek, Mayou and others[23] employ probing or syringing. Peters has, at times, used probes. Parsons, who holds a decided opinion as to the injurious effect of probing in the adult, apparently makes an exception in treating this affection in the young, as he states that a single probing usually brings

about a cure. Mayon[9] believes that aspiration fails to clear the duct when there is congenital narrowing, and says that this view is further borne out by the clinical fact that, if one of these patients "is seen before an abscess forms, one careful passage of a probe is generally sufficient to effect a cure." Jackson, in quoting Weeks'[18] advice simply to cleanse the conjunctival sac and protect the parts until Nature has had a fair opportunity to establish a passage, and if this has not occurred at the end of two months to slit the canaliculus slightly and pass a small Bowman probe, states that he would not limit to two months, or even six months, the period in which it is proper to try milder measures, provided the symptoms are controlled by such treatment.

A successful method, not recommended by any writer, was witnessed by Copez. According to Van Duyse,[11] this author saw a lachrymal tumor rapidly cured by the nurse applying mouth suction to the nose of the infant.

As the possible results of delayed opening of the tear passages may be the occurrence of infection, with its usual sequelæ and dangers, it does not seem to the author a wise procedure to wait on Nature an indefinite period to eliminate this menace; especially as the therapeutic measures advised in the palliative treatment include the continued use of organic salts of silver at home, thus adding to the former dangers the one of argyrosis, the use of massage, a measure to which Ollendorff[10] ascribes the blame for the occurrence of necrosis in one of his cases; also, seemingly, disturbance of the nutrition of the infant (Cutler[21]).

No doubt the danger of allowing Nature to effect the cure would be slight if the patient could be kept under constant supervision, but this is rarely possible, especially when the treatment may be *giving no tangible* results.

As it seems to be the practice of some of these clinicians to use probes to overcome the obstruction when the expectant treatment has failed, it would appear to me that some such procedure is indicated at once, when simple pressure over the sac fails to give permanent relief. Maternal pride shrinks from displaying a pussy-eyed infant to the critical public, and the author has received from no one more grateful thanks than he did from a mother whose infant had been treated expectantly for weeks, and was at once cured by probing.

The result secured by probing in the first case of my series was so brilliant that I pursued the same course in my subsequent cases, and, with one exception, with the same success, namely, disappearance of the trouble after a single probing. In the exceptional instance it was necessary to repeat the probing three times.

Doubtless, for those unaccustomed to passing probes, it would be wiser to counsel measures requiring less skill. For this reason, syringing has been recommended by some, and while it is possible in some cases to force a passage in this way, it does not seem to me to be less difficult than probing, unless the baby be etherized, a measure which I have found unnecessary in passing probes.

Probing here is done under different circumstances from those in lachrymal obstruction in the adult. As a rule, no resistance is met with, and the probe readily follows the natural passage, which, according to Mayon,[9] is inclined much more backward than it is in the adult, a probe making an angle of about 45 degrees with the forehead when passed through the duct.

DISCUSSION.

Dr. Edward Jackson, Denver: The classification given under the heading of etiology covers the ground thoroughly. But if we consider the lachrymal passages in general, including the adjoining bony and cartilaginous structures as well as the soft parts, all of the causes enumerated, except the conjectural one of pressure of the face during instrumental labor, would be included in faults of development of the passages. Generally the fault is merely a delay in reaching normal development. Failure to develop a lumen, converting the rod of epithelium, which generally marks the site of the lachrymal passages, into a tube, might occur at any point. Most frequently it occurs at the nasal end of the passage; but probably in an important proportion of cases it is one of the so-called valves that fails to become pervious. Some such structures are generally present at some stage of development, but mostly they become pervious before the lachrymonasal septum.

The condition is most likely to be confused with conjunctivitis in the new-born; not with gonococcus conjunctivitis, but with certain subacute or chronic forms that are not rare. In these cases of conjunctivitis the discharge is whitish or gray, the conjunctival sac is likely to present some accumulation of tears, and the persistence of the condition is quite suggestive of lachrymal disease. One is scarcely justified in making the diagnosis of lachrymal obstruction in the new-born unless there is actual evidence of accumulation in the sac and regurgitation of the matter on pressure.

Knowing, as we do, the strong tendency to continued development of the passages and the probability of ultimately securing in these cases completely normal lachrymal apparatus in the end, without operative interference, I watch for complications, and so long as they do not arise avoid any operative interference other than frequent gentle pressure over the lachrymal sac. I have not seen any case of staining from silver salts in infants; but the use of silver preparations is not a necessary part in the expectant treatment of infantile lachrymal obstruction. Solutions of boric acid or sodium chlorid used to cleanse the eye at frequent intervals probably serve the purpose equally well. It is but right that the parents of an infant presenting this condition should be fully *informed of the nature and probabilities of the case*, and allowed to choose whether or not any operative measure should be resorted to. At the same time they should be *informed that the condition could probably be relieved by a* simple probing, and that complications might arise which would render operation urgent. When mechanical interference *is to be resorted to* I prefer the passage of a probe of moderate size through the temporarily dilated punctum. This is not wholly without risk even in skilful hands, but the risk *from attempting to force a* passage with fluid *from a* syringe is at least equally great. Syringing has been looked on as quite safe and conservative, but the permanent staining of the skin by argyrol and the orbital cellulitis with optic nerve atrophy, which have been reported after syringing the lachrymal passages are serious possibilities. The risk of mechanical injury at the time of *treatment* seems quite as great with the syringe as with the lachrymal probe.

Dr. S. L. Ziegler, Philadelphia: I think that these cases of congenital occlusion of the duct are sufficiently rare so that we should place on record any that we may have seen. In twenty years I can recall having treated only two cases. The first was a case of dacryocystitis which occurred between the first and second months. There was no involvement other than the dacryocystitis with mucopurulent discharge. The valve of Hasner was probably closed, thus preventing the passage of tears down into the nose. The case occurred fifteen years ago, and I have had occasion to see the young girl within the past year. She has had no further trouble. My treatment at that time was a single rapid dilatation of the duct, which was practically all the treatment that the child had. The second was a case of atresia with epiphora, in which no remedial measures would bring about a passage of the tears. This case was also promptly relieved by rapid dilatation. The parents bring these children to us for relief, and if this is not promptly obtained by remedial measures I think that the question of dilatation is quite within the bounds of conservative surgery.

DR. C. J. KIPP, Newark: I wrote on this subject twenty-nine years ago and am surprised to hear the last speaker say he has seen so few cases. I see cases at least once a month. They come as cases of ophthalmia limited to one eye. In all cases treated within the last ten years I have used simply cleansing and pressure and have not had to use a probe in any case. The cases that come with abscess of the lachrymal sac are those that have been probed by other oculists. Cases that come to me within a couple of weeks after birth are cured in a very short time by simple cleansing and pressure. You must instruct the nurse or mother to exert pressure properly to direct the secretions downward. If you do it yourself you can often feel the obstruction give way. I think that the best plan, even for a skilful oculist, is to avoid probing. You can get along without it. Of course, it makes more of an impression on the mother and friends to use the probe, but it is more beneficial to the patient to use the finger.

DR. HIRAM WOODS, Baltimore: I recall four cases that I have followed very closely. One got well without any treatment whatever. It was simply treated on the expectant plan, expressing the secretion and cleansing, and in two months the whole thing disappeared. The other cases were treated by probing under anesthesia. In two cases one single probing effected the cure. In one of the cases a difficulty arose in getting a probe down into the nose. The small No. 2 Bowman passed a short distance, then stopped, and it was impossible, without exerting more pressure than I cared to use, to introduce it further. It occurred to me that the difficulty might be a catarrhal swelling of the mucous membrane. After two weeks of waiting a third attempt took the probe directly into the nasal cavity without effort and the case has remained well now for six months. I think that it is extremely important to realize in the introduction of probes into the infant lachrymal duct that when mucous secretion has persisted there is possibility of a good deal of swelling in the lower end of the duct and rough manipulation may do a good deal of harm.

DR. W. ZENTMAYER, Philadelphia: In my first case the patient had been treated by a local ophthalmologist for catarrhal conjunctivitis. An immediate cure followed the passing of a probe. It was the gratitude of the mother in this case that caused me to pursue the treatment advocated in my paper in subsequent cases. It is very unpleasant for a mother to have an infant with a purulent eye to show her friends and she is grateful for having it cured by a single treatment. Dr. Jackson says that he would treat a member of his own family in the expectant manner. So would I, because I should have the patient under constant observation. In practice this is not possible, and if the treatment is giving no results, the patient is apt to be neglected and serious trouble may supervene. In the Rostock clinic and in the private practice of Professor Peters, but seventeen cases were observed between 1901 and 1908; so that the condition can not be considered a common one. Mayou, whose experience has been large, states that if these cases be seen before an abscess forms one careful passage of a probe is generally sufficient to effect a cure. Dr. Woods' difficulty in passing a probe in his case may have been due to that condition referred to in the fifth division of the etiology, "partial occlusion by pressure of the inferior turbinate bone."

The Ocular Tuberculin Reaction.—E. Waldstein in the *Prag. med. Wchnschr.*, Feb. 27, 1908, xxxiii, 9, warns against the use of the tuberculin ocular test in cases in which disease of the conjunctiva exists. He says that the reaction in such cases is much more severe than in sound eyes and may cause inconvenient results. The cutaneous method of von Pirquet, in which a healthy skin is expressly stipulated, is therefore preferable as it in no way endangers the health of the patient, while the conjunctival reaction often extends beyond the desired limits and sometimes causes permanent lesions.

THE CORRELATION OF CLINICIAN, PATHOLOGIST AND LAYMAN.*

BOND STOW, A.M., M.D.
Pathologist, Metropolitan Hospital, Blackwell's Island.
NEW YORK.

Medicine has two fundamental objects in view, of equal and vital importance: first, the immediate relief of human suffering and the restoration of the individual to his normal standard of health; second, the protection and maintenance of the members of society in this normal state. The first strictly concerns the clinician, the second the hygienist.

Hygiene, although strictly founded on scientific medical data, nevertheless, so intimately is associated with many intricate sociologic problems that we recognize it as a science distinct and apart from medicine in its more restricted significance.

I wish to center your thought more particularly on clinical medicine or that intimate association between physician and patient in the diagnosis and treatment of disease, as well as to point out the inestimable service rendered both laity and the profession by the pathologist, the clinician's inseparable companion.

Virchow recognized the clinician as the close and confidential agent of the pathologist, as it is he who garners the data from life which the latter is to combine with those of his studies as he forges the chain of our understanding of morbid phenomena. The clinician must guard the truth and accuracy of his findings as carefully as the pathologist does the facts elicited by his work, so that when these combined data are received in the final summing up of the evidence the conclusions to be drawn therefrom shall rest on trustworthy premises.

The one can not be regarded as the superior of the other, for both reciprocally are dependent as they struggle in their respective spheres each to search out and collect the evidence which united deciphers Nature's hieroglyphics.

The clinician is often confronted with an array of symptoms as occult and intricate as the solution of a Chinese puzzle. It becomes his duty to separate the primary from the secondary symptoms, carefully to place each in its proper perspective, and therefrom logically to deduce a true conception of the actual underlying pathologic processes involved, for which he is to advise rational means that are to remove the cause and hence the effect. A comprehensive understanding of the etiology of disease, a vast bedside experience, in conjunction with a thorough knowledge of the fundamental truths of pathology, compose the tripod on which he must stand before attempting to solve the mystery. Even then the task is not always a simple one.

The clinician who is privileged to have his bedside conclusions reviewed by the pathologist is indeed fortunate, for thereby his errors become rectified, and after repeated humiliating disclosures stern necessity compels the cultivation of that spirit of intelligent criticism and conservatism so essential for mastery over the difficult details of medical science.

But he who knows not the blessings of pathologic criticism may go on and on, year after year, committing the same error over and over again because of the lack of this acquaintanceship with the pathologist, who, though occasionally quite discomforting to an oversensitive soul, yet nevertheless remains the clinician's best about a cure. Mayou[9] believes that aspiration fails to clear the duct when there is congenital narrowing, and says that this view is further borne out by the clinical fact that, if one of these patients "is seen before an abscess forms, one careful passage of a probe is generally sufficient to effect a cure." Jackson, in quoting Weeks'[13] advice simply to cleanse the conjunctival sac and protect the parts until Nature has had a fair opportunity to establish a passage, and if this has not occurred at the end of two months to slit the canaliculus slightly and pass a small Bowman probe, states that he would not limit to two months, or even six months, the period in which it is proper to try milder measures, provided the symptoms are controlled by such treatment.

---

* Read before the Medical Society of the County of New York at its stated meeting, March 23, 1908.

A successful method, not recommended by any writer, was witnessed by Copez. According to Van Duyse,[11] this author saw a lachrymal tumor rapidly cured by the nurse applying mouth suction to the nose of the infant.

As the possible results of delayed opening of the tear passages may be the occurrence of infection, with its usual sequelæ and dangers, it does not seem to the author a wise procedure to wait on Nature an indefinite period to eliminate this menace; especially as the therapeutic measures advised in the palliative treatment include the continued use of organic salts of silver at home, thus adding to the former dangers the one of argyrosis, the use of massage, a measure to which Ollendorff[10] ascribes the blame for the occurrence of necrosis in one of his cases; also, seemingly, disturbance of the nutrition of the infant (Cutler[21]).

No doubt the danger of allowing Nature to effect the cure would be slight if the patient could be kept under constant supervision, but this is rarely possible, especially when the treatment may be giving no tangible results.

As it seems to be the practice of some of these clinicians to use probes to overcome the obstruction when the expectant treatment has failed, it would appear to me that some such procedure is indicated at once, when simple pressure over the sac fails to give permanent relief. Maternal pride shrinks from displaying a pussy-eyed infant to the critical public, and the author has received from no one more grateful thanks than he did from a mother whose infant had been treated expectantly for weeks, and was at once cured by probing.

The result secured by probing in the first case of my series was so brilliant that I pursued the same course in my subsequent cases, and, with one exception, with the same success, namely, disappearance of the trouble after a single probing. In the exceptional instance it was necessary to repeat the probing three times.

Doubtless, for those unaccustomed to passing probes, it would be wiser to counsel measures requiring less skill. For this reason, syringing has been recommended by some, and while it is possible in some cases to force a passage in this way, it does not seem to me to be less difficult than probing, unless the baby be etherized, a measure which I have found unnecessary in passing probes.

Probing here is done under different circumstances from those in lachrymal obstruction in the adult. As a rule, no resistance is met with, and the probe readily follows the natural passage, which, according to Mayou,[9] is inclined much more backward than it is in the adult, a probe making an angle of about 45 degrees with the forehead when passed through the duct.

DISCUSSION.

Dr. Edward Jackson, Denver: The classification given under the heading of etiology covers the ground thoroughly. But if we consider the lachrymal passages in general, including the adjoining bony and cartilaginous structures as well as the soft parts, all of the causes enumerated, except the conjectural one of pressure of the face during instrumental labor, would be included in faults of development of the passages. Generally the fault is merely a delay in reaching normal development. Failure to develop a lumen, converting the rod of epithelium, which generally marks the site of the lachrymal passages, into a tube, might occur at any point. Most frequently it occurs at the nasal end of the passage; but probably in an important proportion of cases it is one of the so-called valves that fails to become pervious. Some such structures are generally present at some stage of development, but mostly they become pervious before the lachrymonasal septum.

The condition is most likely to be confused with conjunctivitis in the new-born; not with gonococcus conjunctivitis, but with certain subacute or chronic forms that are not rare. In these cases of conjunctivitis the discharge is whitish or gray, the conjunctival sac is likely to present some accumulation of tears, and the persistence of the condition is quite suggestive of lachrymal disease. One is scarcely justified in making the diagnosis of lachrymal obstruction in the new-born unless there is actual evidence of accumulation in the sac and regurgitation of the matter on pressure.

Knowing, as we do, the strong tendency to continued development of the passages and the probability of ultimately securing in these cases completely normal lachrymal apparatus in the end, without operative interference, I watch for complications, and so long as they do not arise avoid any operative interference other than frequent gentle pressure over the lachrymal sac. I have not seen any case of staining from silver salts in infants; but the use of silver preparations is not a necessary part in the expectant treatment of infantile lachrymal obstruction. Solutions of boric acid or sodium chlorid used to cleanse the eye at frequent intervals probably serve the purpose equally well. It is but right that the parents of an infant presenting this condition should be fully informed of the nature and probabilities of the case, and allowed to choose whether or not any operative measure should be resorted to. At the same time they should be informed that the condition could probably be relieved by a simple probing, and that complications might arise which would render operation urgent. When mechanical interference is to be resorted to I prefer the passage of a probe of moderate size through the temporarily dilated punctum. This is not wholly without risk even in skilful hands, but the risk from attempting to force a passage with fluid from a syringe is at least equally great. Syringing has been looked on as quite safe and conservative, but the permanent staining of the skin by argyrol and the orbital cellulitis with optic nerve atrophy, which have been reported after syringing the lachrymal passages are serious possibilities. The risk of mechanical injury at the time of treatment seems quite as great with the syringe as with the lachrymal probe.

Dr. S. L. Ziegler, Philadelphia: I think that these cases of congenital occlusion of the duct are sufficiently rare so that we should place on record any that we may have seen. In twenty years I can recall having treated only two cases. The first was a case of dacryocystitis which occurred between the first and second months. There was no involvement other than the dacryocystitis with mucopurulent discharge. The valve of Hasner was probably closed, thus preventing the passage of tears down into the nose. The case occurred fifteen years ago, and I have had occasion to see the young girl within the past year. She has had no further trouble. My treatment at that time was a single rapid dilatation of the duct, which was practically all the treatment that the child had. The second was a case of atresia with epiphora, in which no remedial measures would bring about a passage of the tears. This case was also promptly relieved by rapid dilatation. The parents bring these children to us for relief, and if this is not promptly obtained by remedial measures I think that the question of dilatation is quite within the bounds of conservative surgery.

Dr. C. J. Kipp, Newark: I wrote on this subject twenty-nine years ago and am surprised to hear the last speaker say he has seen so few cases. I see cases at least once a month. They come as cases of ophthalmia limited to one eye. In all cases treated within the last ten years I have used simply cleansing and pressure and have not had to use a probe in any case. You must instruct the nurse or mother to exert pressure properly to direct the secretions downward. If you do it yourself you can often feel the obstruction give way. I think that the best plan, even for a skilful oculist, is to avoid probing. You can get along without it. Of course, it makes more of an impression on the mother and friends to use the probe, but it is more beneficial to the patient to use the finger.

Dr. Hiram Woods, Baltimore: I recall four cases that I have followed very closely. One got well without any treatment whatever. It was simply treated on the expectant plan, expressing the secretion and cleansing, and in two months the whole thing disappeared. The other cases were treated by probing under anesthesia. In two cases one single probing effected the cure. In one of the cases a difficulty arose in getting a probe down into the nose. The small No. 2 Bowman passed a short distance, then stopped, and it was impossible, without exerting more pressure than I cared to use, to introduce it further. It occurred to me that the difficulty might be a catarrhal swelling of the mucous membrane. After two weeks of waiting a third attempt took the probe directly into the nasal cavity without effort and the case has remained well now for six months. I think that it is extremely important to realize in the introduction of probes into the infant lachrymal duct that when mucous secretion has persisted there is possibility of a good deal of swelling in the lower end of the duct and rough manipulation may do a good deal of harm.

Dr. W. Zentmayer, Philadelphia: In my first case the patient had been treated by a local ophthalmologist for catarrhal conjunctivitis. An immediate cure followed the passing of a probe. It was the gratitude of the mother in this case that caused me to pursue the treatment advocated in my paper in subsequent cases. It is very unpleasant for a mother to have an infant with a purulent eye to show her friends and she is grateful for having it cured by a single treatment. Dr. Jackson says that he would treat a member of his own family in the expectant manner. So would I, because I should have the patient under constant observation. In practice this is not possible, and if the treatment is giving no results, the patient is apt to be neglected and serious trouble may supervene. In the Rostock clinic and in the private practice of Professor Peters, but seventeen cases were observed between 1901 and 1908; so that the condition can not be considered a common one. Mayou, whose experience has been large, states that if these cases be seen before an abscess forms one careful passage of a probe is generally sufficient to effect a cure. Dr. Woods' difficulty in passing a probe in his case may have been due to that condition referred to in the fifth division of the etiology, "partial occlusion by pressure of the inferior turbinate bone."

The Ocular Tuberculin Reaction.—E. Waldstein in the *Prag. med. Wchnschr.*, Feb. 27, 1908, xxxiii, 9, warns against the use of the tuberculin ocular test in cases in which disease of the conjunctiva exists. He says that the reaction in such cases is much more severe than in sound eyes and may cause inconvenient results. The cutaneous method of von Pirquet, in which a healthy skin is expressly stipulated, is therefore preferable as it in no way endangers the health of the patient, while the conjunctival reaction often extends beyond the desired limits and sometimes causes permanent lesions.

THE CORRELATION OF CLINICIAN, PATHOLOGIST AND LAYMAN.*

BOND STOW, A.M., M.D.
Pathologist, Metropolitan Hospital, Blackwell's Island.
NEW YORK.

Medicine has two fundamental objects in view, of equal and vital importance: first, the immediate relief of human suffering and the restoration of the individual to his normal standard of health; second, the protection and maintenance of the members of society in this normal state. The first strictly concerns the clinician, the second the hygienist.

Hygiene, although strictly founded on scientific medical data, nevertheless, so intimately is associated with many intricate sociologic problems that we recognize it as a science distinct and apart from medicine in its more restricted significance.

I wish to center your thought more particularly on clinical medicine or that intimate association between physician and patient in the diagnosis and treatment of disease, as well as to point out the inestimable service rendered both laity and the profession by the pathologist, the clinician's inseparable companion.

Virchow recognized the clinician as the close and confidential agent of the pathologist, as it is he who garners the data from life which the latter is to combine with those of his studies as he forges the chain of our understanding of morbid phenomena. The clinician must guard the truth and accuracy of his findings as carefully as the pathologist does the facts elicited by his work, so that when these combined data are received in the final summing up of the evidence the conclusions to be drawn therefrom shall rest on trustworthy premises.

The one can not be regarded as the superior of the other, for both reciprocally are dependent as they struggle in their respective spheres each to search out and collect the evidence which united deciphers Nature's hieroglyphics.

The clinician is often confronted with an array of symptoms as occult and intricate as the solution of a Chinese puzzle. It becomes his duty to separate the primary from the secondary symptoms, carefully to place each in its proper perspective, and therefrom logically to deduce a true conception of the actual underlying pathologic processes involved, for which he is to advise rational means that are to remove the cause and hence the effect. A comprehensive understanding of the etiology of disease, a vast bedside experience, in conjunction with a thorough knowledge of the fundamental truths of pathology, compose the tripod on which he must stand before attempting to solve the mystery. Even then the task is not always a simple one.

The clinician who is privileged to have his bedside conclusions reviewed by the pathologist is indeed fortunate, for thereby his errors become rectified, and after repeated humiliating disclosures stern necessity compels the cultivation of that spirit of intelligent criticism and conservatism so essential for mastery over the difficult details of medical science.

But he who knows not the blessings of pathologic criticism may go on and on, year after year, committing the same error over and over again because of the lack of this acquaintanceship with the pathologist, who, though occasionally quite discomforting to an over-sensitive soul, yet nevertheless remains the clinician's best friend. This correlation of clinical medicine and pathology is wisely acknowledged abroad both by the profession and by the laity and acted on accordingly, whereas here in America as yet it receives but scanty recognition.

---

* Read before the Medical Society of the County of New York at its stated meeting, March 23, 1908.

With these introductory remarks, let us turn our attention to the inductive method of diagnosis, cursorily passing in review the two premises which constitute the basis of our bedside conclusions, the anamnesis and the status præsens. I shall try to point out a few striking instances of the erroneous diagnoses which frequently occur because these premises are too carelessly considered or even negligently disregarded.

The value of an accurately gathered anamnesis is of as much importance to the physician as the shrewd sifting of testimony is to the lawyer. Frequently when the clinical symptoms are too few or misleading we must rely quite implicitly on the anamnesis alone.

It is not easy to obtain a history sufficiently trustworthy to form the major premise on which to rest a diagnosis. Too great caution can not be taken to keep our patients in a calm confidential attitude so that the truth may be elicited without omission or modification from pride, fear, forgetfulness or overstimulated imagination.

Our interrogations should be as simple, clear, logical and few as the necessity of the individual case demands, for confusion in our minds inevitably will be reflected in the minds of our patients. Each statement should be accepted only after the most critical examination. The anamnesis, in some cases, of necessity must extend to the collateral branches of the family to trace the influence of the now universally accepted law of atavism.

Unfortunately, history-taking in some of our hospitals is frequently done in a perfunctory, hurried manner. This branch of the work is usually entrusted to the younger members of the house staff, who are as yet new and inexperienced and often show a sad tendency to slight this rather irksome yet, nevertheless, most important task for the more spectacular scenes of the bedside or operating amphitheater.

It would appear judicious for the profession to appoint a commission, composed of both clinicians and pathologists of long practical experience, to formulate some general plan of history-taking, strictly relevant and compendious, yet sufficiently comprehensive to meet the fullest requirements of medical science, so as to be accepted as a standard by all public hospitals.

The resultants of the work in our various hospitals must be combined into ultimate conclusions which shall represent the standards of medical thought and practice. The starting point for such a combination of forces is the standardizing of all hospital anamneses. The goal will be attained after the laity are educated to the point of placing reason above sentiment and permitting science to complete on the dead body the search for truth begun during life. When such ideal conditions prevail here in America then the statistics and generalizations of scientific medical data from our hospitals will be the more accurate and acceptable because of the vastly increased number of cases recorded under the one and same general plan of work.

Passing now to the status præsens or the physical examination of the patient, we find here a field productive of the widest differences among physicians. Hasty observations, with their ill-drawn conclusions, overconfidence, and, in many instances, common ignorance of pathologic anatomy, owing to the comparatively infrequent autopsies in this country, are among the causes for these differences.

No symptom can be too trivial to be neglected, for often an apparently insignificant symptom far distant from the seat of disease gives the sole clew that leads to a correct diagnosis.

It is a most mortifying as well as a serious error to assign as cause of pain in the knee some simple form of synovitis, and fail to detect an incipient coxitis; or to diagnose a sudden severe lancinating pain in the right hypochondriac region as due to cholelithiasis, and possibly operate for gallstones when simply dealing with a reflex pain caused by an attack of angina pectoris; or hastily to diagnose a daily hectic fever with slight amount of purulent sputum as an ordinary bronchitis, when a careful microscopic examination of the sputum would have disclosed the *Ameba coli* that came from a previous attack of dysentery, which, having caused an abscess of the liver with perihepatitis, finally ruptured into and produced an abscess of the lung; or to associate repeated attacks of epigastric pain and vomiting with simple catarrhal gastritis, when an examination of a twenty-four hour specimen of urine would have shown slight traces of albumin, with hyalin and granular casts, and thus enlightened the physician as to the true meaning of the uremic storm signals set up by an advancing interstitial nephritis.

Clinicians can not exercise too great care in establishing the reality of each concrete fact, whether positive or negative, that forms the basis of their bedside conclusions.

If the boundaries of the heart are asserted to be enlarged, or if a bronchial respiration exists at the base of a lung, or if it is positively affirmed that an empyema, for example, does not exist, or that a urinalysis proves to be negative, there must be no uncertainty of such premises, for thereon depends a conclusion that may be the means of saving or losing a human life.

I was recently confronted at the autopsy by a diagnosis proved to be wholly in error, simple because I did not pay sufficient heed to one of my major premises. On the following symptoms I had ventured a diagnosis of cerebellar tumor: Double choked disc, vertigo, cerebral vomiting, ataxia, increased and irregular respiration and pulse, loss of intelligence, difficult hearing and gradual muscular atony; urinalysis asserted to be negative so far as trace of albumin, casts or kidney epithelium. Signs of edema were absent.

The autopsy proved entire absence of any cerebral tumor. There was a slight cerebral edema, an acute hydrocephalus, and a chronic interstitial nephritis. Thus the symptoms of uremia were mistaken for cerebellar tumor because the evidence of a negative urinalysis was accepted from another, while there is no doubt a painstaking and searching examination would have given positive tests for albumin, casts, and possibly kidney epithelium, and thus at once would have revealed the true significance of the symptomatology.

Another source of error in diagnosis lies in the too hasty association of ideas. In a malarious district not every inhabitant with an enlarged spleen and an occasional fever necessarily has malaria; not every painter that comes complaining of cramps and obdurate coprostasis has chronic lead poisoning; not every cook that consults with reference to a hematemesis has a gastric ulcer.

Thus the knowledge gained by the occasional association of certain trades with certain diseases is directive but by no means conclusive, and it is precisely in such cases that our analysis of the symptomatology and etiology of any specific case should be the more exhaustive and critical. These are the cases that demand shrewd judgment and draw on our largest resources if we are to give the proper values and deduce rightful conclusions.

The acquirement of the so-called "diagnostic glance" is solely obtained by a long patient schooling in this inductive method of diagnosis. It teaches us to grasp the important factors in any case and from them the lines of investigation that must be pursued and others that may be omitted for the want of time.

An abscess of the lung suddenly developing in the course of previous indefinite cerebral symptoms, as headache, somnolence, spasms, chills, and an irregular temperature, arouses at once a suspicion of lateral sinus suppurative thrombosis; whereas the same set of symptoms arising in a case of bronchiectasis, with the well-known drumstick fingers, a stinking sputum and hectic flush, should demand a thorough examination of the fundus of the eye for choked disc due to cerebral abscess.

Well-marked symptoms of indigestion, icterus, headache and extreme nervousness in a woman at full term would suggest acute yellow atrophy of the liver; but these same symptoms in a young despondent foreign girl of the working classes, instead of being a case of simple catarrhal jaundice, may be a case of phosphorus poisoning induced for the purpose of committing an abortion.

In emergency cases (particularly when coma is present) this well-developed "diagnostic glance" is of incalculable service. Here the physician must comprehend at a glance and act on premises rapidly if not too securely laid.

The work of the master in this respect is no trick of legerdemain, but the result of his thorough unerring knowledge gained through years of training in the inductive method of diagnosis and the fearless verification of those bedside conclusions at the autopsy. But humiliating, indeed, will be the experience of one attempting this rapid snapshot diagnosing who has not had the prerequisite bedside and postmortem training.

The failure thoroughly and systematically to examine our cases by the inductive method often leads to painful disclosures. The discovery of one lesion is no reason to cease searching for others, but on the contrary should be a stimulus for the discovery of complications or other independent primary lesions.

Among my autopsy experiments one pre-eminently illustrates the results of hasty clinical observations. A drunken man, run over by a wagon, had been brought into the hospital. After a hasty examination no lesion of a serious nature was diagnosed. A pleuropneumonia developed and the case was transferred from the surgical to the medical ward. Death intervened and the autopsy, performed by one of Europe's master pathologists, demonstrated a pleuropneumonia in consequence of twelve fractured ribs, six on either side. There was also found a complete fracture of one of the dorsal and one of the lumbar vertebræ, none of which lesions, according to the record, appear to have been diagnosed in life.

Although this represents an extreme case, nevertheless, reviewing my bedside and postmortem experiences, I can recall many instances occurring with painful frequency where eminent clinicians have been accused of the most egregious mistakes simply because pressed for time, the overcrowded conditions of our hospitals prevented each patient from receiving the requisite care and attention his case demanded for a successful scientific issue.

This brings up a present burning question in regard to our hospital services: Why have we not more physicians on our hospital staffs; and why is not better and more scientific work demanded of each, together with quarterly or semi-annual reports accurately summarizing the work done in each department so that the profession generally may become a beneficiary? Not all are privileged to receive hospital appointments, but those denied such positions of power are none the less entitled to the full knowledge derived therefrom, not through the occasional spasmodic efforts of the few, but through regular complete reports stamped with official authority, detailing with equal impartiality and minuteness both the failures and causes thereof, as well as the commendable successes.

Public hospital appointments should be regarded as positions of trust, and the scientific emoluments resulting from such trusteeship as the common property of the entire profession. Only men especially endowed with natural talents, education and executive ability, actuated by a true love of science rather than personal preferment, should be chosen as the profession's trustees to such positions.

Furthermore, as evidence of their right and fitness for such trusteeship original scientific contributions gleaned from their individual fields of labor should be demanded of them by the general profession as its eminent right and privilege.

The satisfactory accomplishment of such scientific work in our overcrowded charity institutions would require a greater number of workers in proportion to the patients so that closer attention to detail might be given. Such an increase of workers, for harmony's sake and better scientific results, naturally would necessitate the abandonment of our present antiquated hospital methods for newer and more centralizing ones. Each ward would require one chief of staff permanently appointed and empowered to apportion the work and to summarize the results therefrom for use by the general profession, instead of each attending physician assuming this rôle. Not every one is fitted to act as administrative head.

The period of service would need extension, particularly in chronic cases and those of perverted metabolism, for often to-day in our public hospitals unfortunate results follow the bi-monthly and tri-monthly changes of our attending physicians, who often differ in matters of diagnosis and treatment, with the result that the patients suffer.

The rarity of autopsies in our country and the lay prejudices against them emboldens clinicians to formulate unwarranted and speculative conclusions and to be content with diagnoses that would not be tolerated if they knew that a thorough autopsy must be held in case of death. Our hasty, superficial methods sometimes lead to results by which the profession must feel humiliated. For example, take this instance, reported in the *New York Sun*, Aug. 17, 1907:

Hospital Censured.

CORONER'S JURY SAYS PATIENT DID NOT GET PROPER TREATMENT.

Coroner Harburger and a jury held an inquest yesterday into the death of David Rodesky, the painter who died in the insane asylum on Ward's Island on July 29 from blood poisoning.

Rodesky fell off a surface car and injured his foot. Through neglect the wound became infected. He was sent to Bellevue friend. This correlation of clinical medicine and pathology is wisely acknowledged abroad both by the profession and by the laity and acted on accordingly, whereas here in America as yet it receives but scanty recognition.

With these introductory remarks, let us turn our attention to the inductive method of diagnosis, cursorily passing in review the two premises which constitute the basis of our bedside conclusions, the anamnesis and the status præsens. I shall try to point out a few striking instances of the erroneous diagnoses which frequently occur because these premises are too carelessly considered or even negligently disregarded.

The value of an accurately gathered anamnesis is of as much importance to the physician as the shrewd sifting of testimony is to the lawyer. Frequently when the clinical symptoms are too few or misleading we must rely quite implicitly on the anamnesis alone.

It is not easy to obtain a history sufficiently trustworthy to form the major premise on which to rest a diagnosis. The period of service would need extension, particularly in chronic cases and those of perverted metabolism, for often to-day in our public hospitals unfortunate results follow the bi-monthly and tri-monthly changes of our attending physicians, who often differ in matters of diagnosis and treatment, with the result that the patients suffer.

The rarity of autopsies in our country and the lay prejudices against them emboldens clinicians to formulate unwarranted and speculative conclusions and to be content with diagnoses that would not be tolerated if they knew that a thorough autopsy must be held in case of death. Our hasty, superficial methods sometimes lead to results by which the profession must feel humiliated. For example, take this instance, reported in the *New York Sun*, Aug. 17, 1907:

Hospital Censured.

CORONER'S JURY SAYS PATIENT DID NOT GET PROPER TREATMENT.

Coroner Harburger and a jury held an inquest yesterday into the death of David Rodesky, the painter who died in the insane asylum on Ward's Island on July 29 from blood poisoning.

Rodesky fell off a surface car and injured his foot. Through neglect the wound became infected. He was sent to Bellevue

Hospital and then to the insane asylum. The jury found this verdict:

> "We censure the Manhattan State Hospital and Bellevue Hospital for failure to give the deceased proper treatment while in their care, and recommend that the Manhattan State Hospital increase the number of their attendants and adopt a system of reports to show the exact status of every patient at all times, making it possible for the authorities to ascertain at any time who is in charge of a patient."

Does it not seem wiser for the profession to demand a higher grade of work than to chafe under the slurs and humiliating criticisms of a public too often outraged by the unfortunate results occasionally following the independent hasty observations of the self-overburdened few?

Considering the difficulty of obtaining correct data as to the anamnesis and the status præsens, it is not strange that even experienced physicians occasionally commit serious errors because, through carelessness, overconfidence or lack of time, they pay too little respect to these premises. Nothnagel admitted that he felt himself quite fortunate when he proved to be correct in 60 per cent. of his diagnosis of difficult cases. It should not be forgotten that his every bedside conclusion was recorded and in case of death had to receive the judicial stamp of a rigid autopsy. Under similar conditions it is probable that not many clinicians would improve on this record.

This brings us to the consideration of one of the important topics of this address, namely, the value to both laity and profession of diagnosis when reviewed by the autopsy.

> Suppose under the influence of a strong public sentiment it was the prevailing custom for each case of death to be examined as to the cause thereof. What must be the ultimate and inevitable effect of such a practice? Would it not quickly expose the charlatan with his obnoxious nostrums and offensive advertising, lay bare the false claims of the numerous pseudo scientific delusions under which yearly many lives ruthelessly are sacrificed, and weed out the unfitted by natural selection under the operation of that most inexorable of all laws?[1]

Such a custom should be in force to-day, at least with respect to all patients dying in our charity institutions. In private practice public sentiment should be educated to the point of demanding an autopsy at least in all cases that defy an explanation free from speculation. In such cases the necessity of an autopsy is a positive duty, for the living are entitled to those secrets of the dead which alone can elucidate morbid phenomena. This is the sole invaluable service the dead can render the living. The laity becomes the great beneficiary of the raising of the professional standard which would result.

Pathologic anatomy is the force to-day disturbing the contentment and dry-rot in medicine engendered under the former régime of empiricism. It teaches us the abundant recuperative resources of Nature, thereby more and more emphasizing our own limitations and demonstrating the truth that all our therapeutics should be simplified and founded on more rational scientific bases, and employed only to assist Nature in overcoming insurmountable obstacles. This is neither hopeless therapeutic nihilism nor *do nothing* irresponsible fatalism, but rather the advocacy of a still closer study of the inimical forces about us and a more singular purpose in employing those of our protective agencies tried and not found wanting. Science to-day with its ever-increasing exactness demands that the intelligent use of any drug shall be the same as the skilful conservative use of the scalpel.

Pathologic anatomy is no respecter of persons, "pathies" or "isms," but an impartial moderator in all scientific controversies over somatology. It is pathologic anatomy that teaches us the transcendentalism and futility of high potencies; that curbs the reckless extravagant use of the prescription blank; that disillusionizes those misguided mental therapeutists who attempt cures in defiance of natural law and order. In a word, it is pathologic anatomy that levels the barriers that divide into schisms what should be one great united fraternity, and compels all schools, standing shoulder to shoulder on a common basis, to recognize that the science of medicine is subject to that one great universal law which controls all other phenomena in the natural world—the law of cause and effect.

If we are to remain in darkness, cloaking our mistakes with the mantle of vain assumption, as we frequently do to-day in the absence of a verifying autopsy, then let the present deplorable indifference continue. But if we would seek the light, surrendering self to science by thinking harder, speaking less frequently, but fearlessly and willingly facing our conclusions when spoken, thus having a little less of the personal factor in our work and a little more earnest searching for the hidden truths of medicine; if we would advance and maintain our noble profession in a position commanding the high respect and sincere veneration it should, but unfortunately often does not, receive to-day, as evidenced by the numerous pseudo-scientific "isms" flourishing among us; if we would protect both the laity and ourselves from our ever-recurring mistakes—thus silencing the criticisms and aspersions too often deserved, that our faith-curists and other enemies cast on us—then, harmoniously working together, clinician, pathologist and layman, let us welcome the invaluable knowledge to be gleaned solely from the respectful scientific autopsy of our reverenced dead.

214 West Seventieth St.

[1] Darwin: Law of the Survival of the Fittest.

TYPHOID FEVER.

A SUMMARY OF 148 CASES WITH REFERENCE TO THE EFFICACY OF THERAPEUTIC FASTING.

R. M. HARBIN, M.D.
ROME, GA.

Autointoxication and inanition are the Scylla and Charybdis of a typhoid patient, and the physician who can pilot the charge through the narrow channel of safety, should be accorded a high degree of therapeutic skill.

For the treatment of typhoid fever a specific remedy has not been discovered, and the consensus of opinion is that medicines have but little more than a contributory effect in the management of this disease. So the drug treatment may be eliminated altogether from this discussion.

The process of using bacterial vaccines for hastening the process of immunization by increasing the phagocytic property of the blood, thus raising the opsonic index, a process which also takes place in a normal case of typhoid fever, is rational and scientific and deserves a more extended application. In other words, the processes of Nature are expedited by this method.

---

* This paper, read at the Fifty-ninth annual session of the Medical Association of Georgia, Fitzgerald, April 15, 1908, is a continuation of some studies, a report on which was read at the New Orleans session of the American Medical Association, and published in THE JOURNAL, July 11, 1903.

At present it is universally agreed that the food factor in the management of a typhoid patient is the most important practical question to be solved. In this day of progressive medicine there is a tendency to wander away from convictions that have been evolved from years of bedside study. It is reasonable to suppose that the newer methods of research would reveal certain fallacies that have resulted from clinical observations, but it is unreasonable to admit that old clinical conclusions could be displaced by bedside studies of the present day, for it is doubtful that clinical observers of recent years are in any way superior to our medical forefathers.

Bacteriologic investigations have not caused us to discard many of the old clinical methods of management of typhoid fever, but, on the other hand, have enabled us to confirm and perfect the technic of treatment given by our predecessors. It is safe to say that the lowered mortality rates are now more due to that factor than to any other cause, excepting possibly the serum treatment. Of course there has been great advance in prophylaxis.

Our apology for offering these observations is that the heavy mortalities from the accepted form of treatment of typhoid fever are unwarrantably high. One of the best known surgeons in America a few years ago made the statement publicly that in one year a number of his family connection had died from typhoid fever, and had had the best medical service available; and further said that if he were to contract the disease he would prefer that some intelligent country physician should manage the case. Such comments are not uncommon.

As this summary is offered from the standpoint of a clinician, it is well to refer to certain clinical facts relating to this disease.

Typhoid fever is a disease of early adult life, the average age in this series of cases being 21 years. Extremes of age show less susceptibility, as do also the anemic.

Robust individuals seem to be more susceptible and furnish the more violent types of the disease, which is probably due to a peculiar susceptibility and to the fact that more infection is consumed. Of the total number there was 27 per cent. of cases classed severe between the ages of 20 and 30 years, while the percentage of severe cases among others was 12.4. There was a greater amount of toxemia associated with those exhibiting gastrointestinal symptoms, showing a direct relation between the extent of pathognomonic lesions and the constitutional symptoms. Of the fifty-seven severe cases, forty-five, or 78.7 per cent., gave marked gastrointestinal symptoms, while in the mild cases the percentage was 15. We have similar conditions in diphtheria, in which the extent of pathognomonic lesions, as a rule, bears a direct relation to the systemic disturbance. The toxin of the *Bacillus typhosus* is liberated by the disintegration of the organism, and takes place more rapidly in the human organism than in culture media.[1] The bacilli found in the feces represent those that have escaped absorption, and are probably a small percentage of those existing in the digestive tract. "In typhoid fever the bacillus first found its way from the alimentary tract to the lymphopoietic system, including the spleen, where it developed chiefly, and from it invaded the blood stream. They thought it doubtful if the bacillus multiplied in the blood, but believed that its presence there represented simply an overflow from the lymph organs."[2] So we would conclude that the battleground of treatment lies in the vicinity of the small intestines.

More characteristic symptoms are displayed in diarrheic cases, while the opposite is true of the constipated cases. A contrast of symptoms may be noted in the second week, where watery diarrhea exists, and a week later, when the bowels become constipated; yet the patient has been taking the same food and running the same temperature, while the symptom-complex has markedly changed. The excessive activity of purgatives is evidence of contraindication to this class of remedies, and as diarrheic cases tend to constipation, temperatures become lowered and, as a rule, general improvement follows.

Emaciation occurs independently of the amount of food taken into the stomach,[3] and this suggests the fact that but little food is assimilated, while the remainder furnishes a culture medium for the *B. typhosus* and other bacilli, thus giving rise to a mixed infection, resulting in a greater degree of toxemia. While the specific typhoid toxin is associated with high temperatures, it is not a constant accompaniment, as a patient may improve under a higher temperature. Tympanites and diarrhea are distressing complications, and under these circumstances it is almost criminal to give more than minimum quantities of the blandest forms of nourishment, for the absorption of food is almost *nil*. Because of an increased area there is increase of the absorption of toxins, while there is a transudation of fluids out of proportion to the intake of liquids, and whatever food is given under these circumstances usually excites peristalsis in the effort to eliminate the surplus. We know that under normal conditions peristalsis is essential to absorption, and in this abnormal condition it is reasonable to believe that peristalsis still increases absorption of toxic substances, and clinical observation warrants this conclusion. Feces usually consist principally of excretions from the intestinal walls.[4] Where there is toxic paralysis of this function the process of elimination and absorption is disturbed by any food residue, and one of the first signs of improvement in a case of typhoid fever is the appearance of feces in the dejecta. The use of purgatives will not force the presence of bile and feces, but aggravate a condition already established by the disease. It is frequently noticeable that a purgative or enema temporarily raises the temperature, which was not directly dependent on constipation, and this fact is not to be noted in any other acute gastroenteric disorder.

Ambulatory cases are not, as a rule, any less prone to intestinal complications than others, for obvious reasons. In fact, the diagnosis of typhoid fever is frequently made only after the occurrence of a fatal hemorrhage or perforation. Hemorrhage in an unsuspected case of typhoid fever often initiates a typical course of the disease because of the establishment of conditions favorable for the increase of intestinal symbiosis. Septic products from the decomposition of blood in the intestinal canal probably constitute a greater danger than the immediate loss of blood entails.

Of the seven fatal cases, four occurred in those primarily classed mild, and in one a fatal hemorrhage revealed the diagnosis. A late diagnosis is often responsible for the untoward course of a typhoid case.

The younger the patient, the milder the course of the disease. There were but three of the fifty-seven severe cases in patients under 10.

If the onset is sudden and severe, the duration will be shorter. The degree of pyrexia is not necessarily an index of gravity.

Pulse frequency, barring individual peculiarities, is an index of danger.

Delirium, when due to hyperpyrexia, has not as bad a significance as that occurring with a low temperature. Abortive cases show a greater tendency to relapse than others, probably because the organism has not had time to produce a sufficient amount of its own antitoxin. There were five relapses, or 3.3 per cent. of the total number of cases, and all were associated with some unusual gastrointestinal disturbances. This percentage is far below the average. The variety of types of this disease is more due to individual conditions than to variation in types of epidemics. There may be only one severe case in the family with others.

The first discernible sign of improvement is a notable increase of urine.

Clinical diagnoses were principally relied on in these cases. Cabot concludes[5] from extensive postmortem examinations that 97 per cent. of all cases of continued fever in the New England states lasting two weeks or more proved to be typhoid, tuberculosis or sepsis. From an investigation by Dr. H. F. Harris[6] of forty-five cases of "slow fever" in southern Georgia the typhoid bacillus was isolated in 51.1 per cent., the paratyphoid bacillus in 20 per cent. and a mixed infection in 2.29 per cent. of cases. The commission appointed to investigate the outbreak of typhoid fever during the Spanish-American war recognized the existence of continued fevers as belonging to the malarial and typhoid classes only. The Widal reaction is only confirmatory. So we would conclude from the available scientific data that clinical diagnoses can be made with a reasonable degree of accuracy. It is very necessary to make a diagnosis during the first week of typhoid fever, for the subsequent course is materially influenced by the management of the disease during this period of time. Every case of continued fever lasting a week or more without obvious cause should be assumed to be typhoid fever.

In those liberally fed a great majority of deaths from typhoid fever result, directly or indirectly, from gastrointestinal complications, and this would lead us to regard the dietetic management one most important part of treatment. As in all diseases for which there is no specific remedy, the aim should be to treat the patient and not the disease, for the patient in some cases of typhoid fever will recover under an abusive form of treatment, while in others the small thread of vitality can be conserved only by a precision of the most delicate management. In any case, however mild, the aspect of the disease may become suddenly changed by some intestinal complication. This leads us to the consideration of the food question.

The great desideratum is to nourish the patient without increasing saprophytosis. It would appear that a patient having vomiting and diarrhea would do better without food altogether for a time, while food could be taken *ad libitum* in another case without such disturbances. While a majority of the latter class would do well, a certain number would be changed to the former class. In a twenty years' experience I have not acquired a therapeutic skill that enables me to say which case will do well on a free diet. Previous to this series, which covers a period of twelve years, we have treated a number of cases on a liberal diet, with painful mortalities, so we must adopt a course that has fewer hazards. A small percentage of these cases were given liberal feeding where conditions were exceptional. It is a question of saving the greater number, for a small percentage of mortality is inevitable. When we can discover a preventable cause that produces death we should endeavor to apply the knowledge in subsequent cases. In fact, the majority of deaths are theoretically preventable. Of the seven deaths, four could have been prevented.

The proper food management will well-nigh shield a case of typhoid fever from the usual dangers incident to the disease. "Clinical typhoid is really in many instances a comparatively mild original infection, plus a fatal intestinal toxemia due to saprophytosis, plus inanition,"[7] and it is our belief that more patients die from saprophytosis than from typhoid infection. "Typhoid fever, especially in the later stages, was largely autointoxication."[8] It is absurd to try to maintain any standard that approaches a normal nitrogen metabolism in an acute infectious disease having gastrointestinal lesions, for the patient's life does not depend on it. A patient weighing 120 pounds requires 1,925 calories a day in health. In infectious diseases there is an increased waste of nitrogen, but it is advisable to give as much food as possible without increasing the amount of autointoxication. Fats and carbohydrates in excess do not prevent tissue waste, which is the inevitable consequence of the disease, regardless of the proteid content of the food.[9] That being true, a surplus of food would cause hyperpyrexia. So it is incumbent on the physician to keep his patient alive, by avoiding the dangerous effect of overfeeding, until individual immunity is established. Milk may be a digestible, or it may be the worst food. My inability to decide what cases are suitable to its use has led me to discard it altogether, for nothing is so disastrous to an intestinal ulcer as a milk curd. Mandel[10] has observed that in milk-fed fever patients the temperature rises or falls with the quantity of purin bases eliminated, and Lusk suggests the possibility that medicinal antipyretics nullify the activity of purin bases on the nerve centers because these remedies do not lower the temperature under normal conditions. The clinical observation has been recorded that milk is inadmissible in any form of hyperpyrexia, more especially that arising from gastrointestinal disturbances. It has been our observation that milk as food will not accomplish in the South what it is said to do in New England in the treatment of gastroenteric disorders. It is doubtful if the average man in health could digest the classical two quarts of milk a day when abruptly placed on that diet alone. It may be diluted, however, to obviate the danger of curd formation.

Therapeutic fasting—not starving, an incorrect term frequently used—serves an admirable purpose in allowing a typhoid case to pursue a more nearly normal course, for fasting is effectual by reducing the bacterial content of the alimentary tract, thus becoming a negative intestinal antiseptic. By such means we establish conditions more favorable for feeding. As the more violent types are seen in sthenic cases, this class furnishes the more favorable subjects for fasting, which is the only remedy we have for reducing a case more nearly to a normal typhoid infection. Fasting before abdominal operations is effective by reducing the number of intestinal bacteria. Kelly[11] advises fasting for the same reason in plastic operations of the intestines. "Cusing and Lovingood examined twenty-seven dogs and eight rabbits. They found that the duodenum, jejunum and upper part of the ileum were nearly always sterile after a fast. . . . Where patients have been subjected to preparations for an operation, the usual period of fasting has a marked tendency to reduce the bacterial content about the ileocecal valve."[12] Emaciation may not be any more marked in patients that have fasted than in others. Frequently the reverse happens, for nutrition is cell activity, and typhoid fever is not more fatal when accompanied by emaciation, for cell activity in sthenic cases may be paralyzed by toxins. In convalescence, gain in weight may be obtained on the same quantity of food, because cell activity seems to be stimulated by Nature's antitoxin. Metabolism is a function of the cell and is increased by autointoxication.

The pathologic nature of tuberculosis and typhoid fever are very similar. The conclusion is established that the mixed infection, and not the tubercle bacillus alone, produces the hectic fevers, sweats, etc., which exhaust a tubercular patient. The tubercle bacillus plays only an initial part in the morbid process. In typhoid fever the initial lesion is caused by the *B. typhosus,* which opens up an area for the multiplication of other micro-organisms and absorption of their toxins. One truth clearly established in the successful treatment of pulmonary tuberculosis is the necessity for the enforcement of absolute rest of the respiratory organs as far as possible. Reasoning by analogy, we should endeavor to give as much rest as possible to the intestines in typhoid fever, and clinical evidences bear out this assumption. If pathognomonic lesions were away from the alimentary tract, forced feeding would be rational. In the treatment of typhoid fever we may apply with benefit Ochsner's rationale in the management of cases of acute appendicitis, his aim being to keep intestines in a passive state by fasting, thus reducing bacterial symbiosis, and by insisting on absolute bodily rest. In these two diseases increase of peristalsis is a means of distributing infection—in one disease, inside, and in the other, outside the intestines. The two conditions are essentially surgical.

> Hence the conclusion was reached that in typhoid fever, and other infectious diseases, an important part of the morbid process consisted in a disturbance of nitrogen metabolism which was very similar to that seen in pure autointoxication, and which, therefore, was not directly connected with the toxins of the invading bacteria. The excessive nitrogenous metabolism in typhoid fever was not the specific effect of the action of the endotoxins of the typhoid bacilli, but represented hyperactivity of a normal type, associated with fever. Wolf had pointed out that bacterial endotoxins were much alike in their actions, and affected chiefly the nervous system.[13]

The pathologic anatomy of typhoid fever shows a condition of gastrointestinal catarrh with hyperplasia, with a great reduction of all the digestive fluids. Saliva is diminished or absent, and hydrochloric acid is usually absent in the gastric juice, and, in fact, almost every condition unfavorable to digestion exists. Diarrhea is an effort of Nature to throw off what the intestines can not assimilate. Intestinal ulcers should be assumed to exist in every case, however mild, and the proper treatment of ulcers is rest.

The rational treatment of such a condition is a restricted diet, or fasting; then peristalsis can be better controlled by cold applications, and an opiate may be used if much diarrhea exists.

It has been our observation that the use of opium retards tissue waste during a fast, and in these cases it was prescribed when any indication arose, especially insomnia. Prof. Lafayete B. Mendel, professor of physiologic Chemistry in the Sheffield Scientific School, in a personal communication, says:

> The few available experiments on man regarding the influence of morphin on metabolism indicate no change in the respiratory exchange when therapeutic doses are given. The studies on animals have indicated a slight decrease in nitrogenous metabolism with small doses, and an increase with distinctly larger doses in starvation. It seems probable, from the small amount of experimental evidence available at present, that the doses used for your patients would exert no marked effect on their nitrogenous exchanges.
>
> Drugs may influence the course of metabolism, iodothyrin increasing it and morphin profoundly diminishing it.[14]

Death from starvation occurs ordinarily in eight days after the withdrawal of all food and water. The same result occurs, even though dry food is allowed, but life is prolonged forty days when water is freely given.

In sthenic cases fasting should be applied from one to three days until the active symptoms are controlled. Gentzen proved by experiment that fasting does not arrest the secretion of hydrochloric acid.[15] The reduction of the degree of toxemia is hardly noticeable the first day, but is shown by a reduction of one or two degrees of temperature on the second day, and on the third day more than that; but it is exceptionally advisable to continue fasting through the third day, as the severe symptoms are usually ameliorated. In other than sthenic cases, that is, in pregnancy, the puerperium, the tubercular diathesis, the anemic, senile cases, etc., fasting should not be applied, but in these cases there is rarely a necessity for its use. On the advent of pneumonia the patient should have more liberal feeding, because of increased demands for food. An argument obtains that fasting and a restricted diet enhance the effects of hydrotherapy, the technic of which will be referred to later. Full feeding in many cases results in the necessity of packing the patient in ice to control fever. Those violent toxic cases show marked improvement after a twenty-four hour fast, which allows the organism to unload the excessive amount of toxemia.

Many cases run an abortive course after the amphibolic period under a treatment by fasting and a restricted diet. After fasting twenty-four to forty-eight hours, a very restricted diet should be given, consisting of broths of beef, chicken, mutton, oysters, etc., coffee, cocoa, egg albumin, peptonoids, gelatin, etc., in prescribed amounts.

The effect of these slops should be carefully watched, and definite quantities should be ordered in severe cases. It is needless to say that they can be taken *ad libitum* in mild cases. The popular custom of water-logging the system is to be deprecated, and if the patient is rational his inclination would be a reliable guide. Lusk says that the ingestion of quantities of water causes a true increase of proteid metabolism.

Gelatin is a valuable adjuvant in the dictary of a typhoid patient. It serves three purposes: it adds to the relish of the various liquids, lessens the nitrogenous waste from the system and prevents hemorrhage. A teaspoonful three or four times a day is the amount usually ordered and should be dissolved in a little hot water and then added to any liquid nourishment, meat broths, cocoa, coffee, tea., etc., or else flavored with wine or lemon and served with whipped cream. It adds richness of taste to these slops, which otherwise become tiresome to the patient. An agreeable sherbet may be made by combining gelatin with white of eggs with 20 per cent. of cream and sweetened and flavored to taste. The food value of gelatin, which, being in a concentrated form, serves an excellent purpose, is recognized.

Prof. Lafayette B. Mendel writes me in this connection: "Gelatin plays the same rôle as the carbohydrates in sparing tissue waste," and cites a conclusion by Dr. J. R. Murlin:[16]

> The power of the organism to utilize gelatin as a substitute for proteid in maintaining nitrogen equilibrium depends to some extent on the proteid condition of the body at the time of the experiment. The lower the proteid condition becomes, the more strongly does the organism lay claim to gelatin as a means of protecting its living substance. Herein appears a biologic adaptation of no small importance.
>
> Gelatin spares proteid in metabolism.[17]

When used emaciation is less rapid. The hemostatic effect of gelatin is universally recognized, but to wait until an intestinal hemorrhage has occurred but little immediate good can be hoped for by its use. It should be used as a routine in all cases to prevent hemorrhage. Very aggravated diarrheic cases do not tolerate it so well, as it may increase tympany. But in these cases it may be used on alternate days in small quantities. In the last seventy-three cases in which routine gelatin feeding was given no case of hemorrhage occurred after having been under treatment two days.

The case should be closely studied. Any surplus of food will be indicated by a rise of temperature, for to nourish the patient without overcharging the digestive capacity requires a very close study. Milk should be absolutely forbidden, because no one can predict when it will form a curd, which is worse that solid food. One of my patients had a hemorrhage in convalescence from taking milk and lime water in equal parts. I examined curds the size of a hazelnut in the bloody dejecta. The case was a mild one.

Another patient was seen in consultation, with symptoms of perforation, twenty-four hours after drinking two glasses of buttermilk at an interval of half an hour. He died three days later from peritonitis. This case was a mild one.

Milk is valuable, however, diluted with two to five parts of coffee, cocoa, broths, hot water, as under these circumstances the danger of curd formation is slight, unless contradicted by diarrhea and tympany.

This plan of dietetic treatment should be continued until active symptoms are controlled, and as improvement advances nourishment may be more liberally given. Solid food is a danger that offers few advantages to the patient. Nearly all recrudescences are due to dietetic errors. Fasting in late stages and convalescent stages will cause fever, as inanition often causes fever. The subsequent history of patients subjected to fasting has been in no way different from that of those more liberally fed.

As before suggested, fasting and a restricted diet greatly enhance the effect of hydrotherapy. Where there is fermentation in the alimentary canal with hyperpyrexia it is easy to understand how difficult it is to reduce the temperature by baths, but under other conditions the modified bath is effective, whether cold, tepid or hot.

I have often observed a reduction of more than two degrees of temperature after a single sponge bath in sthenic cases after fasting.

To illustrate: The patient in Case 94 fasted the first day and was then allowed a very restricted diet. There were given thirteen cold sponge baths, lasting from twenty to thirty minutes. The greatest reduction of temperature was 2.4 degrees, while the lowest was 0.8 of a degree, and the average 1.8 degree per bath. We would not expect to find such results under other circumstances. Constipation should be relieved on alternate days by a soapsuds enema.

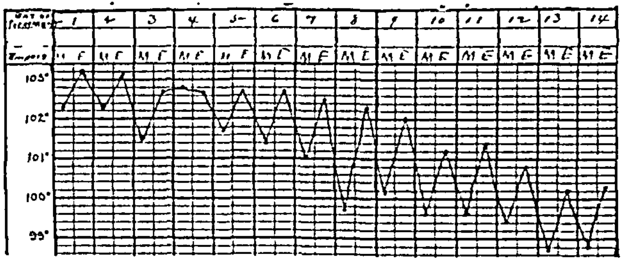

Chart 1.—A composite temperature chart of ten cases of typhoid fever.

TABLE 1.

Averages of 10 cases of uncomplicated typhoid fever under treatment by a restricted diet and fasting. These cases are taken at random from those lasting 14 days or more and do not include abortive cases.

Case No.	Sex.	Age.	Severe.	Gastrointestinal symptoms.	Nervous symptoms.	Duration, days.	Mortality.
72......	F.	17	+	+	—	33	..
80......	F.	14	+	+	—	14	..
81......	M.	20	—	—	—	15	..
82......	F.	18	+	+	—	20	..
88......	M.	5	+	+	+	14	..
93......	M.	25	+	+	—	15	..
94......	M.	24	+	+	—	21	..
95......	M.	23	—	—	—	16	..
96......	F.	26	+	+	+	30	..
98......	M.	26	—	—	—	14	..
Average		19.8	70. %	70. %	20. %	19.2	0 %
Average of entire series of 148 cases.....		21.	38.5%	39.9%	16.2%	17.4	4.7%

There are many minor details in the treatment of certain symptoms and complications that need no mention and are familiar to every clinical observer.

I append a chart of an abortive case (Case 108) in which the diagnosis was confirmed on the eleventh day by the Widal reaction. On the third day there was active delirium, with unconsciousness and diarrhea with tympanites. The notes on the chart need no comment.

In this report cases lasting twelve days or less were classed as abortive, and there were forty-nine cases, or 33.1 per cent. of this type, which is a greater proportion than ordinarily expected.

Abortive cases show a greater tendency to relapse, and require to be kept in bed on a restricted diet at least ten days after a normal evening temperature.

---

[16] Am. Jour. Physiol., 1907, xix, 285.
[17] Lusk: Science of Nutrition, p. 102.

Of the total number, 144 were white and 4 black. Patients under 10 years, 23; between 10 and 20 years, 43; between 20 and 30 years, 54; and over 30 years, 28. There were 80 males and 68 females. The average duration of these cases was 17.4 days, that is, up to the time when the evening temperature became normal. Gastrointestinal disturbances were noticeable in 59 and absent in 89 cases. Nervous symptoms were marked in 24 cases and absent in 124 cases. Eleven cases, or 7.4 per cent., were complicated. Five patients, or 3.3 per cent., had hemorrhages, four of which were slight and one immediately fatal from coming out of bed during delirium. It may be remarked that two of these had hemorrhage before coming under treatment. Two patients had two attacks within twelve months. Pneumonia occurred as a complication in three cases; one had osteomyelitis, one hematuria, and one showed mental imbecility during convalescence, but recovered promptly. One case showed hyperpyrexia, the temperature reaching 106.7 F. and during the following week remaining subnormal. No case of perforation or thrombosis was diagnosed. Two patients had double parotitis and recovered. In one the parotid glands sloughed out *en masse*. The treatment adopted in the other case deserves some notice. A man 30 years old developed double parotitis in the third week, with symptoms of profound sepsis and collateral edema quite closing the eyes. Under chloroform anesthesia the glands were incised and a grooved director was passed in six or seven different directions through the edematous tissue of the gland to the depth of an inch or more. Symptoms of sepsis were ameliorated and swelling rapidly subsided without suppuration. Two weeks later orchitis developed. Three years previous he had had mumps, followed by orchitis. Among the seven deaths patient 46, a negro, died from urinary retention and neglect. Patient 57 died from hemorrhage in a few hours from getting out of bed, not having a nurse. Patient 70 died on the tenth day after convalescence, from pneumonia. There were no evidences of typhoid reinfection. Patient 64, a negro, alcoholic, died on the twelfth day, from asthenia. Death in Case 118 resulted from osteomyelitis after a month's duration. Patient 120, an ambulatory type, before coming under treatment, had hemorrhage, which determined a fatal issue. Patient 124, the wife of this man, being depressed with grief, died a month later, complicated with pneumonia. Of the 144 whites there occurred five deaths, or 3.4 per cent.

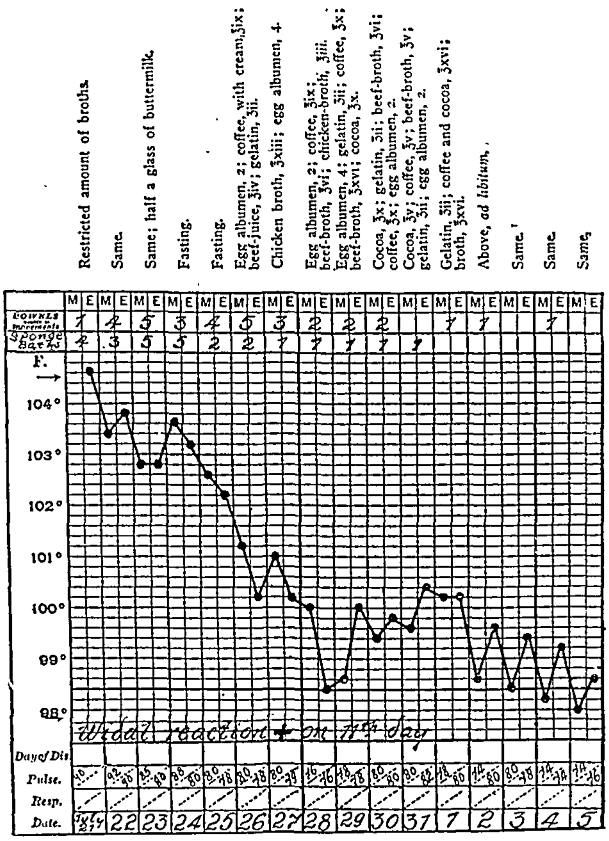

Chart 2.—Chart of an aborted case of typhoid fever; the record begins on the second day of the disease and ends on the seventeenth day.

CONCLUSIONS.

1. The food factor in the treatment of typhoid fever is the most important practical question to be solved.

2. Toxemia is more marked in cases having gastrointestinal disturbances.

3. Clinical evidences warrant liberal feeding only in a few cases.

4. The chief source of development of the *B. typhosus* is found in the intestinal canal and the lympho-poietic system.

5. The aim should be to nourish the patient without increasing saprophytosis, and the battleground of treatment lies in the gastrointestinal tract.

6. A greater danger exists from a toxic paralysis of nutritive activity of the cell than from inanition.

7. Any vital organs containing pathognomonic lesion of an infectious disease demand absolute rest.

8. The excessive nitrogenous waste in typhoid fever is not due to the endotoxins of the typhoid bacillus but probably mixed infections, and the specific typhoid toxin is not necessarily accompanied by high temperatures.

9. Emaciation occurs independently of the amount of food taken and results more rapidly from toxemia than from any lack of nourishment.

10. The patient's life does depend on attempting to maintain a normal nitrogen metabolism.

11. The proper food management will shield a patient from the usual dangers of typhoid fever.

12. Sthenic cases furnish the more dangerous types of the disease, and these are more amenable to therapeutic fasting.

13. Ambulatory cases are not less prone to intestinal complications than others.

14. A greater danger arises from septic conditions set up by a hemorrhage than the mere loss of blood entails.

15. Symptoms are no guides as to the presence of intestinal lesions, consequently patients require more or less routine feeding.

16. Abortive cases show a greater tendency to relapse.

17. Tympanites furnishes an increased area for absorption, and is provoked by any surplus of food, which increases peristalsis.

18. The great desideratum is to treat the patient and not the disease.

19. Scientific data prove that clinical diagnoses may be made with a reasonable degree of accuracy.

20. Therapeutic fasting allows an uncomplicated typhoid infection to pursue a normally mild course without any mixed infection, by reducing the bacterial content of the intestines. This was applied only to the severe cases.

21. Fasting will enhance the effect of hydrotherapy, and frequently render the use of antipyretic measures unnecessary.

22. Gelatin is a valuable food in that it lessens the nitrogenous waste and prevents hemorrhage.

23. The low mortality in this series of cases was greatly due to the elimination of relapses and complications among the mild or abortive cases by restricted feeding and lessening the dangers in sthenic patients by fasting.

24. In this report forty-five consecutive cases occurred without a death. Of the 144 whites, five, or 3.4 per cent., died, and the low mortality, 4.7 per cent., of all cases was ascribed to the dietetic management, though many of the cases had very inefficient nursing.

MIGRAINE, AN OCCUPATION NEUROSIS.*

GEORGE LINCOLN WALTON, M.D.
Consulting Neurologist, Massachusetts General Hospital.
BOSTON.

It is not claimed that this paper will present a complete explanation of migraine; it is hoped, however, that it will start a suggestive line of thought bearing on a pathogeny which can be at the best only hypothetical.

The form of migraine to which I shall confine myself is the every-day type, the variety which I have found occurring in complete form in 17 per cent. of healthy young adults, and in incomplete form in many more. It reaches its greatest intensity in early life and generally disappears after middle life. It is often preceded by scotomata, by temporary aphasia and numbness, loss of memory, signs of mental incapacity and confusion, and even possibly, as Gowers suggests, by the peculiar feeling that the present is a reproduction of the past, the feeling thus described by Coleridge:

> Oft o'er my brain does that strong fancy roll
> Which makes the present (while the flash doth last)
> Seem a mere semblance of some unknown past,
> Mixed with such feelings as perplex the soul
> Self questioned in her sleep.

Any of these symptoms may appear without the pain in the head. Loss of consciousness never occurs, a fact which sharply distinguishes migraine from epilepsy, though there have been attempts to make them analogous. The frontal and temporal regions are most often involved, the occipital next often, the vertex practically never alone.

At the time of greatest intensity the pain is sometimes accompanied by nausea and vomiting, especially in early life, whence the term "sick headache." The time varies in duration from several hours to a day or more. It does not often materially interfere with sleep, though it frequently appears on awakening in the morning. It does not necessarily accompany extreme use of the eyes, though it is apt to appear after such use, as on the morning following a theater party.

The so-called ophthalmoplegic form of migraine is so rare in comparison with this form, and so distinct in its symptoms, that it seems hardly fair to discuss both types together. The suggestion of Plavec,[1] that the ordinary form is the precursor of the ophthalmoplegic form, seems to have little basis, and his proposed pathology (periodic swelling of the hypophysis) as concerns the ordinary migraine, is purely speculative.

A case reported some years ago by Dr. Cheney and myself has a practical bearing on this question. A man of middle age had suffered many years from what was supposed to be the common type of migraine, though it was accompanied by the unusual symptom of persistent homonomous hemianopsia. The headaches became more severe, various paralyses appeared, mental deterioration ensued, and death followed. The autopsy revealed pituitary tumor.

While this case bears favorably on Plavec's location for ophthalmoplegic migraine, it is far from aiding us in the pathogeny of ordinary migraine. Nor does it suggest that ordinary migraine was the precursor of the more serious trouble. The migrainous headaches in this case should rather be regarded as symptomatic of the local lesion, no more allied to or resulting from ordinary migraine than epileptoid seizures from cerebral tumor are allied to, or result from, idiopathic epilepsy, though they may be mistaken for it at the outset.

Whatever theory is advanced for the pathogeny of ordinary migraine, the use of the eyes can hardly be left out.[2] The arguments connecting the use of the eyes and migraine are easily preponderant. In the first place too many cases of migraine have been relieved, in part or entirely, by correction of refractive error, particularly of astigmatism, to be explained by coincidence. In the second place, attacks have been frequently aborted by the mere straightening of glasses, as I have many times verified in my own case. In the third place, migraine has lessened and disappeared in innumerable cases after accommodative paralysis has appeared. Finally, study of the blind shows that the greater the blindness the less the migraine. My own examination of a long series convinced me that migrainous headaches are only half as frequent among the blind as among individuals of corresponding age and under like conditions.[3]

It may be objected that migrainous headaches are not quite unknown among the blind. But it must be remembered that it is a common practice for the blind, as for others, to adjust their accommodation to the distance of their work as judged, even in the absence of sight, by the position of the hands.

Assuming, then, that disturbance of the accommodative centers plays a part in migraine, it need not be expected that the blind shall be quite exempt.

Another peculiarity of *eyestrain* which has an important bearing on my proposition is the almost continuous frown of the astigmatic. This frown involves principally the corrugator supercilii and the anterior part of the occipitofrontalis, which muscles occupy the regions in which the pain most frequently appears.

If one voluntarily contract the brows for fifteen minutes he will experience a disagreeable sensation which suggests migraine in mild form. This leads to the question whether we must assume the pain of migraine to be entirely intracranial, a doubt emphasized by the recent observations of Cushing[4] showing the non-sensitiveness of the dura, the part to which perhaps more than any other the pain of migraine has been credited. It may assist us to recall a somewhat analogous pain which sometimes appears in the back of the neck and "base of the brain" after long-continued eyework in which the head is held firmly in one position. I have been not infrequently consulted for this pain by persons who have undertaken an uncommon line of work, requiring this posture, the commonest illustration being that of the person who has recently undertaken the position of secretary. This pain so often appears after the completion of the day's work, rather than during the work, that its source is apt to be overlooked. The pain is apt first to appear during the night or in the early morning, and is sometimes decidedly paroxysmal. The only relief is found in discontinuance, or lessening the constancy, of the work (unless, happily, the mere correction of refraction serves the turn). This form of headache is surely muscular rather than intracranial; its analogy to migraine is shown by the fact that it is sometimes preceded by twinkling scotoma.

1. Deutsche Ztschr. f. Nervenheilk., 1907, xxxii.

2. This statement does not apply to the views of those who find in migraine the precursor of vascular disease and cerebral softening. My conception of migraine is widely at variance with theories which include such outcome. When we weigh the isolated cases supporting this proposition against the hordes of cases running an innocuous course, it seems reasonable to assume that these few cases represent either coincidence of migraine and organic disease or symptomatic headaches which resemble migraine.

3. Eye Strain, Its Importance and Its Limitations, Boston Med. and Surg. Jour., June 22, 1905.

This occipital form of headache offers a fair illustration of acute occupation neurosis.

The proposition I have to submit is the following:

Migraine is an occupation neurosis, and involves (1) the visual centers; (2) the centers of accommodation (centers of divergence and convergence in the frontal region); (3) the intrinsic and extrinsic muscles of the globe, and (4) the muscles outside the orbit which are called into play in the effort required for accurate vision, principally the corrugator supercilii and occipitofrontalis, and also the muscles inserted in the occipital region, which serve to steady the head.

In order that we may approach the question fairly, it is important that we start with a clear idea of the symptomatology of occupation neurosis in general; its exact pathogeny is hardly susceptible of analysis.

This is a subject not generally understood. "Writers' cramp" has called attention to one symptom (cramp) which is really neither the most prominent nor the most common. Even writer's cramp has its "neuralgic" form, and in other occupation neuroses pain is not only by far the most prominent, but often the only symptom, the other symptoms, weakness, paresthesia and cramp, following with varying frequency and in varying degrees.

An occupation neurosis is a condition resulting from overuse of certain parts. The most constant symptom is pain, generally referred to the overused muscles, but sometimes extending to other parts. Among the less constant symptoms are muscular spasm and paresthesia. The symptoms may be constant or paroxysmal, and are not always synchronous with the muscular overuse which causes them, but sometimes follows after an interval. The disturbance involves the muscles and the sensory and motor cerebral centers which constitute the overused mechanism.

The following case illustrates a common form of occupation neurosis involving the arm:

Patient.—A woman, aged 30, suffered from pain in the thumb and first finger extending up the forearm, accompanied at night by a numb prickly feeling. She practiced much on the piano, carried a heavy music roll, and often sewed a whole evening without stopping. In short, there was almost constant use, in one form or another, of the hand. There was moderate tenderness of the forearm. There was no objective anesthesia or loss of power. The diagnosis of occupation neurosis was made.

Treatment.—No improvement appeared from simple rest, but when a splint was applied and the arm placed in a sling, thus producing absolute rest, improvement soon appeared, and complete recovery followed. She can now use the hand perfectly, but has learned to keep its use within reasonable limits.

The following case presents a connecting link between such cases and migraine:

Patient.—A successful laryngologist from another state had worked for twenty-five years without vacation. He complained of paroxysms of pain in the left side of the neck and behind the ear, sometimes accompanied by tenderness. The pain would come on when his head was placed in the position of operating, become rapidly unbearable if the posture was maintained, and persist after its discontinuance. It would sometimes come on at an interval after operating. Attempts to read sometimes produced the pain. He had astigmatism with correction by a competent oculist. The condition had naturally given rise to much solicitude, and obvious relief of mind followed the diagnosis of "occupation neurosis." The day following the consultation he spent in and about Boston, and for thirty-six hours was entirely free from pain, an experience which he had not had for some time. On the second day he was feeling so much better that he was tempted to return to his work, notwithstanding my advice for a prolonged abstinence from employment. He was desirous of visiting the Massachusetts General Hospital, and I there introduced him to the throat department, in which he was especially interested. Here he spent about an hour, watching operations, and examining throats. On sitting down to lunch afterward a violent paroxysm of pain appeared and lasted for some time. It recurred during the evening on taking up a paper and putting his head in the position of reading. The evening attack lasted several hours, during which the pain was intense and accompanied by tenderness. The only recourse in this case was absolute cessation from work for many months. He is therefore now taking an extended vacation and reports continued improvement.

This case, like many others which have come under my observation, shows that the pain of occupation neurosis may follow the occupation after an interval, just as that of "theater migraine" may first appear on awakening the morning after attending the theater.

The paroxysmal pain illustrated by such cases of occupation neurosis strongly suggests that of migraine. Nor are the minor symptoms of occupation neurosis wanting in migraine. The analogue of the paresthesia is the scotoma, which represents similarly, disturbance of sensory centers. Analogous to the cramp is the ciliary spasm, to say nothing of the facial spasm which sometimes appears in the lids and spreads to other parts, representing perhaps an effort on the part of the overworked centers to close the eye and relieve the tension. I have seen the most long-standing and obstinate cases of this spasm relieved by the correction of refractive error.

The suggestion that migraine is an occupation neurosis does no violence to the opinion of those who regard all migraine as the result of refractive error, and at the same time may prove more acceptable than the reflex theory to those who insist on the hereditary and constitutional basis of migraine. One need only be reminded that all occupation neuroses are more prevalent among the neurotic and the sensitively organized, in whose families appear the varied signs of feeble resistance. It is surely among this class that we look for migraine —but we have not explained migraine by simply conceding its hereditary tendency.

Furthermore, the theory of occupation neurosis would account for cases of migraine in which the patients have slight error of refraction, but marked psychopathic heredity, and at the same time explain its prevalence among those who have marked error of refraction, since the eyes are here used with an overwhelming handicap, the relief of which may well cause the disappearance of the neurosis.

---

[4] THE JOURNAL A. M. A., March 14, 1908

According to the occupation neurosis theory migraine may even appear without error of refraction, in other words it may result from overuse of the eyes, or, in cases of extreme susceptibility, from moderate use of the eyes, just as writer's cramp may be produced, doubtless, in the absence of a faulty method of writing. The fact is recognized, however, that a faulty method favors writer's cramp, and, similarly, error of refraction is doubtless more potent than any other one factor in the production of migraine.

It is no objection to this theory that some individuals use the eyes continuously without migraine, while others acquire this trouble with comparatively little use of the eyes. The same is true of all occupation neuroses. One individual can practice with immunity on a musical instrument from early morning till late at night; in another individual symptoms of occupation neurosis appear with a few hours' exercise.

It may be objected that no account is taken of the vasomotor phenomena of migraine, a factor on which Eulenberg long ago based his entire theory of the pathology of the condition. But the vasomotor changes, in my view, at least, are so far from constant that they are not to be taken into consideration in the search for causal factors, but are rather to be reckoned, when present, as among the comparatively unimportant accompaniments. This is the view long held by Gowers.

The vasomotor symptoms are not only secondary rather than primary, but, in fact, they are not always present. All suppositions based on dilatation or contraction of blood vessels as a primary cause of migraine lead to theoretical considerations which obscure rather than clarify our ideas of migraine. And, further, all such theories are based on a fallacy, namely, that contraction and dilatation of blood vessels necessarily cause pain. To confute this proposition we need only remind ourselves of the extreme dilatation of blood vessels in the blush of shame or the turgidity of anger, on the one hand, and on the other hand, with the pallor of fear and faintness. Even the extreme degree of vascular spasm which results from cold produces numbness rather than pain. It is true that after exposure to cold with resulting vascular spasm, if warmth is too quickly applied, a vascular dilatation follows which is accompanied by extreme pain, but when we consider the extreme degree of vascular dilatation that produces no pain, it is questionable whether the pain is to be attributed simply to dilatation.

The vomiting is difficult of explanation by the theory offered, but it is not less difficult by any other theory. In point of fact, this symptom is probably not one of the essential features but rather an indirect result appearing generally only in the young and at the height of the paroxysm, representing rather a protective effort on the part of Nature, through producing general and special relaxation, just as fainting may appear at the height of pain, resulting from whatever cause. The fact that relief does often follow the vomiting fortifies this supposition.

CONCLUSION.

Migraine is an occupation neurosis resulting, in individuals of neurotic inheritance, from overuse, or use under the handicap of refractive error, of the parts concerned in vision.

It involves, like other occupation neuroses, disturbance of (1) sensory cerebral centers (those of vision in the occipital region); (2) motor cerebral centers (centers of divergence and convergence in the frontal lobe); and, (3) certain muscles (particularly the intrinsic and extrinsic muscles of the globe, the corrugator supercilii and the occipitofrontalis, and also the muscles which steady the head).

The pain of migraine is not necessarily intracranial, but is localized, in part at least, in the region of the muscles concerned, directly or indirectly, in vision.

DISCUSSION.

Dr. H. Gradle, Chicago: In one-fifth of my records of migraine (headache of periodic occurrence), an ocular origin could be excluded at the start. Of one hundred patients observed by me (consecutive but not selected cases), twenty-two were practically, under ordinary circumstances, relieved of their migraine by glasses as long as they wore them continuously. A few complained again whenever the glasses were omitted. Of these 22 patients, twelve had complained of their eyes, while ten had either not known that their eyes were at fault or had been annoyed only to a trifling extent Among the cured two had hyperopia, five had astigmatism against the rule or with an oblique axis amounting to 0.37 D. or more, and fifteen astigmatism with the rule (0.5 D. in two instances and > 0.5 D. in thirteen cases). An impression that I had gradually formed of the greater significance of astigmatism against the rule or with oblique axis is not fully borne out numerically by an analytic review of these records, but it is again strongly suggested by noting throughout my case books the more frequent coincidence of migraine with lower degrees of astigmatism (0.37 to 0.5 D.) when the meridian of greater curvature was not vertical. It has also seemed significant to me that one-sided migraine occurred strikingly often on the side of astigmatism with oblique or inverse axis in asymmetric cases (three in this series). Cases of migraine exclusively or mainly one-sided are especially instructive when the attacks occur on the side of the astigmatic eye and are permanently avoided by suitable correction (eight times in these twenty-two). It is significant that hyperopia of unequal degree in the two eyes does not provoke one-sided migraine. In fact, simple hyperopia figures only in a small proportion of the fully relieved (as well as the much benefited) cases.

Of the hundred patients, thirty-two were only partially relieved of their periodic headache. The headaches were less frequent or less severe and shorter. A few of these returned after years with the history of a long partial relief, but with recent increase in the attacks, though with optic change.

Twenty-six received glasses that proved useful as far as the eyes were concerned, but which did not influence the migraine. To these twenty-six I ought to add one-quarter (five) of the remaining twenty, who had previously been given correct glasses by others without benefiting the migraine.

The results are:

22 practically cured by glasses.
22 benefited by glasses.
31 not influenced by glasses.
15 not requiring glasses (except simple concave spheres).

Among those merely improved or not influenced as regards the migraine were a number who had besides the typical periodic attacks other forms of headache which were practically cured by their glasses.

An analysis of the imperfect results and failures showed an absence among them of one-sided migraine corresponding to the more astigmatic eye. Yet among the patients least improved there were a few pronounced instances of hyperopia and astigmatism of 1.5 to 2.5 diopters. There was also a scarcity of astigmatism against the rule (or oblique) in the negative series. In those least influenced by glasses there was oftener the history of attacks with fairly regular periodicity dating back to childhood than in the more benefited class of patients. The proportion of simple hyperopia was least among those entirely cured and greater in those only partially influenced

I believe that there are various factors involved in the etiology of migraine Heredity is one of the most constant, but not an invariable one Anemia, poor nutrition want of outdoor exercise and indoor confinement have in many instances coincided with pronounced aggravation In relatively infrequent instances migraine may depend on suppuration of a nasal sinus or the existence of a nasal stenosis In nearly one half of my observations there has been no relation between migraine and the eyes In fact, I have even found the neurosis fairly common among people who do not do much close eye-work Yet in about one third the correction of hyperopia and astigmatism made the patient less liable to migraine or reduced its severity In fully one fifth of my cases the headache could be practically prevented by the use of suitable glasses, when worn continuously

The scintillating scotoma is the symptom which more than any other suggests an ocular origin of migraine—at least to the patient The scotoma does not, however prove the ocular origin of the migraine, as in thirty five instances tabulated from my records I find twenty not requiring or not improved by glasses while nine were benefited and six were cured by spectacles In two of the cured and three of the benefited only hyperopia and not astigmatism needed correction, in several others compound hyperopic astigmatism was found

DR LUCIEN HOWE Buffalo We began by using this term 'migraine" in a most indefinite sense, meaning either one of two entirely distinct diseases, and we are now just beginning to recognize a difference between them We still talk about 'headaches," but that term may mean almost anything Head called attention some time ago to the necessity when we speak of headaches of stating just where that ache is what is its area, and also what is the area of increased or decreased sensibility As long as we talk in a general way about headaches, we are simply increasing the chaos which exists Again, when we speak of the strictly ocular symptoms, we may mean either the condition of the refraction or the condition of the intraocular or of the extraocular muscles, or of both That abnormality may be primarily in either or both of these groups of muscles or may be shown in them only secondarily in the effort to overcome any ametropia which may be present Now, in any given case, if we do not know what those factors are, we are discussing something indefinite, and increasing the confusion of our ideas Headaches especially when localized in the muscles in the frontal region or at the back of the head, are apparently *due to the action* of the accessory muscles of accommodation When we contract the frontal portion of the occipitofrontalis we draw also on the occipital portion That strain can often be relieved, as we know, by proper glasses or by cycloplegics

DR HUGH T PATRICK Chicago The use of the eyes is not an occupation at all, it is a function The idea of occupation implies something acquired for a definite purpose *Occupation* is connected with the artificial conditions of modern living, or, if you like, with the present state of evolution or development of humankind To put an occupation side by side with a thing as remotely as anciently physiologic, as the use of the eys, is, I believe altogether a strained comparison According to my understanding of Dr Walton's abstract, there might be ascertainable eyestrain and there might not be, but the idea was that the migraine might have been produced merely by the use of the eyes in a susceptible individual I believe that this is *an untenable position*, because the use of the eyes is a function just as much as mastication digestion and defecation, and we do not call those occupations at all Of course one may abuse his masticator apparatus or his digestive apparatus, and he may abuse his bowels and if he does he pays the penalty; but to say that a man has an occupation neurosis simply because he exercises, as he is bound to exercise these functions born away back low down in the primordial *something* which was originally the progenitor of man is rather far fetched

DR ALBERT E STERNE Indianapolis We must all recognize the fact that *no organs of the body* are so constantly in function as are our eyes, that considering the innervation of the eye, it is hardly wonderful that irritating effects should expand themselves on the central nervous system, notably the brain, through the medium of the eye I should, however, like *to register a strong objection to considering migraine* as an occupation neurosis, not only on the grounds that Dr Patrick has brought forth, but also on the ground that there is in all probability a very subtle but not well understood relationship between true migraine and epilepsy It is peculiar enough that the subject of migraine and the subject of epilepsy should come into close contact with the oculists so frequently It is possibly due to the fact that there is much to be said from the ophthalmic standpoint in dealing both with migraine and with epilepsy Shall we regard epilepsy as an occupation neurosis? Is *there any similarity, or is there even a remote connection* between migraine and epilepsy? These questions are far from being solved. We have absolutely no knowledge of the pathology of true, essential epilepsy or of the pathology of true migraine We know from certain facts and experiences that the two seem to run hand in hand frequently enough I have seen cases of true migraine, periodic migraine, cease, and in their place I have seen epileptic seizures for a series of years—major seizures at that, not minor—and I have seen these epileptic and epileptiform seizures cease and the migraine become *re established Such conditions are not extremely frequent* but still they occur in sufficient numbers to warrant us in regarding them as possibly allied, though I do not think that they are anything like identical They may, however, be founded on similar causes in any given case On the other hand, they may arise coincidently and independently

DR. D I WOLFSTEIN, Cincinnati The supposed effect of the constant contraction of the occipitofrontalis muscle in case of headache in connection with occupation neurosis would not appeal to me, as in many cases of headache the patients *voluntarily and frequently contract this muscle* with a view to getting relief from the headache, I do not doubt that in epileptics or those who have an epileptic diathesis or tendency occasionally a migrainoid attack may stand in the relation of epileptic equivalent, but I do not believe that migraine and epilepsy are interchangeable and closely related conditions Certainly most of those who suffer from migraine have nothing in their history to lead to the slightest suspicion that they are in any way epileptic I do not believe that migraine is often an occupation neurosis because it would be difficult to say what particular occupation itself causes migraine in a very large per centage of cases Indeed it is more apt to affect people who have no occupation at all I believe that there is a very decided connection in many cases of migraine and disturbance of digestion and that a fair proportion of cases are best treated when we take into consideration the gouty, arthritic, or autotoxic forms of disturbance *Often if we treat these cases* along the lines of improved elimination and alimentation, with the exclusion of those factors which are toxic in character, particularly the digestion of too much meat, good results are obtained In my judgment you will find that many cases of migraine are intimately connected with a disturbance in the digestive tract and that the factor of occupation is not of particular moment

---

Propaganda Against Cancer in Uruguay.—L Calzada in a communication to the *Revista Med del Uruguay*, February 1908, compares the statistics of uterine cancer in various countries, especially in regard to operability It was only 7 per cent in his experience with 187 patients; in France the best statistics *give only 20 per cent* , in Italy, 5 per cent in Holland, 9 per cent He urges sending out circulars to physicians impressing on them the importance of early discovery of cancer, also circulars to midwives urging them to send to physicians all their patients with gynecologic affections, emphasizing their responsibility if they allow lesions to pass undiscovered He also urges education of women by lectures and pamphlets *in regard to the dangers of neglect* of uterine disease, advocating that this propaganda should be initiated and carried on by medical societies or official bodies to avoid opportunity for individual advertising by irresponsible *individuals*

OCULAR COMPLICATIONS OF PREGNANCY.*

HIRAM WOODS, M.D.
BALTIMORE.

In dealing with the ocular complications of pregnancy, I shall try to present the bearing of recent pathologic investigations on the cause of serious eye disturbance. Medical literature shows that there is scarcely an eye disease which has not been more or less directly traced to the pregnant state. Some of these we now know are not distinctively so caused. Pregnancy, at most, increases liability by lessening resisting powers. Power[1] published three interesting papers, claiming that, among other complications, pregnancy produced a definite type of superficial central ulceration of the cornea. With our present knowledge of the rôle of infection in corneal ulceration, it seems more natural to attribute to pregnancy only such influence as is seen after any other severe tax on the system.

The same is true of the supposed tendency to phlyctenular ophthalmia. Asthenopia, with its defective accommodation, short of absolute paralysis, varying muscular anomalies, occasional blurring of vision, may be laid at the door of the general nerve tax under which the pregnant woman lives. One must take into account, too, from the same cause, an increase in a preexisting hysterical habit. Thus, Knies[2] reports cases of temporary blindness, without urinary abnormality or ocular lesion, occurring after unusually painful labor. A patient of Szili's became suddenly blind from the opening of a window in a darkened room, and recovered only after six weeks. Then there are the considerable classes of metastatic ocular infections, of amblyopia from excessive hemorrhage, of lighting up of a latent syphilitic lesion, which would probably have remained quiet but for the overtaxed metabolism. I have seen specific chorioiditis relapse during pregnancy. But in all these cases there is, so far as I can see, nothing that is not observed after numerous other conditions.

Apart from temporary functional derangement, hysterical or neurotic, and diminished tissue resistance, there are certain ocular troubles of intensely serious significance to eyesight and even to life, which are observed with sufficient frequency during pregnancy to make the relation of cause and effect almost certain. For purposes of study, they may, I think, be divided into four classes, based on clinical manifestations: (1) The so-called uremic amaurosis, or sudden and complete blindness, without ophthalmoscopic lesion; (2) The hemorrhagic, exudative and degenerative changes in the retina, occurring in connection with albuminuria, and termed albuminuric retinitis of pregnancy; (3) Temporary or permanent loss of central vision or some portion of the visual field, without retinal lesion, the fundus either appearing normal or showing pallor of some portion of the optic disc; (4) A definite neuroretinitis, with hemorrhages and exudates, but not resembling the albuminuric retinitis.

We may consider each of these separately.

1. *Uremic Amaurosis.*—In its association with pregnancy, the term has the same meaning as in nephritis: sudden occurrence of total blindness (usual form), or great impairment of vision. There may be associated other nervous symptoms, such as headache, vomiting, etc. Pupillary reaction is usually maintained, and Fuchs thinks this proves "that the location of the affection can not be in the eye or the optic nerve, but higher up, i. e., in the brain, which is poisoned by the excretory matters retained in the blood."

No lesion is found in the eye, and while this form of blindness has the gravest possible significance in chronic nephritis, and may be serious in pregnancy, it is usually transitory in the pregnant woman, provided she survives other complications. So far as my observation goes, it is confined, when occurring in pregnancy or parturition, to eclamptic cases, and follows the convulsion. The cause of this blindness is usually attributed to uremic poisoning, dependent on kidney disease.

The name, uremic amaurosis, is applied to cases incidental to pregnancy and parturition, because of the similarity of symptoms in the nephritic and parturient forms of blindness, the usual co-existing albuminuria, and the deeply grounded belief that it is through the medium of the kidneys that pernicious vomiting, puerperal convulsions and blindness occur. Difference in the prognostic significance of nephritic and parturient blindness is generally attributed to the fact that in the former the kidneys are in an advanced stage of disorganization, while in the latter the cause of blindness terminates with labor; but that parturient blindness is uremic and that derangement of kidney structure and function is essential to its production seems the fixed teaching of to-day, so far as our text-books go.

2. *Albuminuric Retinitis.*—The characteristic silvery-white, radiating spots, seen in the perifoveal region and at the disc margin, are too well known to need description. In both chronic nephritis and pregnancy the appearances are practically identical. As is well known, in the former these spots are considered of grave significance, and a fatal termination usually comes within two years. In pregnancy, they may appear as early as the third or fourth month, but usually they are seen toward the close of pregnancy.

According to Fuchs these white patches are made up of "fatty degeneration of the retinal elements and of the cells of the exudate." De Schweinitz states that in the retinitis of pregnancy the type is most often inflammatory, and that with the termination of gestation these inflammatory deposits may subside. It is on this possibility of absorption of inflammatory exudates before destructive processes have occurred in the retina, that we base the better prognosis in this form of retinitis. Hence, there is a practical unanimity of opinion that the only logical treatment is induction of labor. While, however, this is true, and while the kidney lesion of pregnancy, to which the retinal inflammation is attributed, is, as Fuchs says, "benign," there is not in our ophthalmic literature much suggestion of any other pathway from the uterus to the eye than through the kidney. Is this a logical or correct position in view of teaching from modern pathologic investigation?

One finds, in treatises on obstetrics uniform warning about the increased danger from pregnancy to a woman who has chronic nephritis. She is certainly more liable to show remote complications of kidney inflammation than she would be if the extra burden of pregnancy were not put on her. But if she develops uremic blindness or albuminuric retinitis during or at the close of pregnancy, the latter condition can no more be blamed for the complication than other influences which are known to exert a bad effect on chronic nephritis. At most, gestation is only an exciting cause and the complication is really dependent on the antecedent nephritis. The same is true of acute nephritis, from any of its usual causes, developing during gestation. Danger of remote complications or even of a fatal ending are greater. But this is not equivalent to saying that pregnancy can cause real nephritis, or that, in a woman, free from kidney involvement before pregnancy, the latter can so influence kidney structure and function as to produce through them grave ocular complications. Indeed, the weight of opinion seems the other way.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

[1] Lancet, Lond., May 8, 15, 22, 1880.

[2] The Eye in General Diseases.

In the American Text-Book of Obstetrics the author of the chapter on the pathology of pregnancy says: "An acute inflammation of the kidney can not be caused by pregnancy, and is only observed in the rare cases where infective bacteria find entrance to the genito-urinary tract of the pregnant." J. Clifton Edgar states that "the kidney is affected in pregnancy by lesions which stop short of actual nephritis." This lesion is "purely a disease of the renal epithelium which undergoes fatty metamorphosis—a deposit and not a degeneration."

It may be well to speak a moment of the so-called "kidney of pregnancy," a condition to which we are apt to attribute too much importance. J. Whitridge Williams mentions it only incidentally in the first edition of his book, and in the second edition says: "It is a slight degree of nephritis. . . . Such conditions are nearly always connected with the various disturbances of metabolism which will be taken up under toxemia of pregnancy." Edgar says: "There is an affection to which the term 'pregnancy kidney' is familiarly restricted, and which is certainly not due to pressure, nor has it anything in common with ordinary nephritis, whether pre-existent or developing during gestation as a result of exposure or infection. In one sense, the notion of pregnancy-kidney is a negative one, formed after the exclusion of other renal lesions, and including numerous conditions which present little in common." Hirst seems to attach more importance to it than most modern writers, and says: "There is often albuminuria in advanced degrees of the condition. Hyaline and granular casts, with epithelium filled with fat, may be found. The kidneys may prove physiologically insufficient, and there may appear all the symptoms of renal insufficiency observed in true nephritis." Hirst also differentiates between chronic nephritis and the kidney of pregnancy, and says that in the latter the kidney symptoms are usually confined to the last months, while in nephritis they are pronounced at an early stage; and, again, that so far as his experience goes, albuminuric retinitis does not appear in the kidney of pregnancy, unless symptoms point to chronic nephritis.

The question I am trying to present is—are ophthalmologists justified in limiting their conception of the etiology of pregnancy-blindness or retinitis to renal lesions? Pregnancy does produce temporary blindness, and sometimes permanent impairment of vision in women previously healthy. It does cause retinal spots of exudation and degeneration in the same class, and the retinal lesion is usually accompanied by albuminuria. But is albuminuria the pathway to the retinal disease, or is the blindness essentially uremic? The recognized authorities from whom I have quoted might be multiplied, but such a course would only confirm the opinions expressed: (1) That pregnancy itself does not produce nephritis; (2) That the so-called kidney of pregnancy is usually insignificant in its effects. and recovers; (3) That it does not produce what we term "albuminuric retinitis."

We may now study the matter from another point of view. The dimness of vision or blindness in cases which do not show retinal lesion usually comes toward the close of gestation, during or after parturition. Again, the visual defect is one of a symptom-group of which headache, somnolence, convulsive seizures, etc., are members. This array has received the name of eclampsia, and convulsions are its prominent manifestation. As is well known, puerperal eclampsia, or convulsions, was generally thought, until late years, to have a renal origin. This opinion was based on the close resemblance of the puerperal to the nephritic seizures, and the usual presence of albuminuria.

Beyond mention of a few facts it is needless to discuss the reasons for abandoning this theory. Briefly, the insignificant renal changes often found at autopsy, and absence during life of symptoms of renal involvement in cases of eclampsia, started investigations which have led away from the renal theory. Edgar agrees with Williams that the pregnancy kidney is most probably a mild product of toxemia. He adds: "The all-important subject of the connection between this renal lesion and eclampsia is best accounted for by attributing the latter to the toxic state and not to the kindey lesion, which is itself the result of the same or an allied toxemia. There is, moreover, every reason to believe that this unknown toxic state of the blood is not uremia."

In the last edition of his work on obstetrics Williams reviews at length his own work on the pernicious vomiting of pregnancy, first published as a monograph in 1906, and includes the work of Prutz, Schmorl and others. A brief summary of conclusions may be given. In pernicious vomiting there are found hepatic changes identical with those found in acute yellow atrophy of the liver. There is profound necrosis of the central portion of the lobule, while the periphery remains intact. The lesions differ from those observed in eclampsia in which the process is essentially one of thrombosis and begins in the peripheral spaces. Williams urges that the hepatic changes in both pernicious vomiting and eclampsia may account for at least part of the urinary changes through the non-conversion of nitrogenous material into urea and its excretion as ammonia. He continues, "It should not be believed that the essential process consists in the hepatic or renal lesions, but in an underlying toxemia, to which they are due."

To summarize those parts of the work which touch ocular problems, it seems to be the prevailing opinion (1) That eclampsia of parturition is not uremic; (2) that both eclampsia and pernicious vomiting are results of a toxic substance circulating in the blood whose nature, or natures, are unknown; (3) that these toxic substances are capable of profoundly affecting the liver, and do so in a much more characteristic way than they do the kidneys; (4) that these substances can produce thrombosis in many of the smaller vessels with consequent degenerative and necrotic changes in various organs.

This conception of the serious complications of pregnancy, if confirmed, will put renal complications in the list of toxic effects. It will also influence our conception of these renal complications as the cause of ocular disturbances. The question will arise whether the toxemia which produces the renal, hepatic and other lesions may not also produce the ocular disturbances and lesions. If eclamptic convulsions are not uremic, except in cases of aggravated pre-existing nephritis, it seems more logical to attribute the temporary blindness of eclampsia to the toxemia of the latter, than to bring in an uremia whose existence is at the most hypothetical. A toxic substance capable of causing such profound nerve disturbances as convulsions and many of the sequelæ might affect the optic centers as well. And, as a matter of fact, we know that these centers are often affected, sometimes permanently, by toxic agents having no connection with uremia.

SECONDARY EFFECTS OF TOXEMIA.

The secondary effects of a toxemia are many; edema, exudation, thrombosis, apoplexy, etc., are among them. They affect the nervous system as well as other parts. Among 65 eclamptic autopsies Schmorl[3] noted thrombi in the smaller cerebral vessels in 58. Edema, hyperemia, etc., were practically constant.

Bearing these facts in mind, we may for a moment look at what we term the albuminuric retinitis of pregnancy. I think all of us have seen nearly identical appearances in patients without albuminuria. I have seen them in a chlorotic girl, with functional menstrual trouble, clearing up with improvement in general health. There was no albuminuria. I have seen them in an apparently healthy boy, without known cause, who later developed a chorioiditis of exudative type in the other eye. In a case of neuroretinitis from venous thrombosis during pregnancy the characteristic retinal spots were evident. Yet there was no albuminuria.

Dr. James Bordley has been making careful study of ocular changes in cases of brain tumors at the Hopkins Hospital. He tells me that he has studied two hundred cases, but at this writing has tabulated only half. Yet in sixteen he found spots in the retina which he would have called albuminuric. The urine was normal. Diagnosis of intracranial neoplasm was confirmed by operation or autopsy. He and Dr. Cushing attribute the retinal changes to pressure, edema, exudation and consequent degeneration without inflammatory processes. All these are logical results of toxemia.

We have, then, the facts that other conditions than albuminuria can produce the characteristic clinical retinitis which has been called albuminuric; that among these are effects produced by toxemia, and that it is to a toxemia that kidney changes in pregnancy are attributed; that in cases in which premature labor has been induced, cure of the retinal lesion has followed. I do not think it is going too far if one urges, with evidence at hand, that we cultivate at least an open-mindedness regarding the causation of what we have always termed the albuminuric retinitis of pregnancy. Such a state of mind has one very important bearing on therapeusis. So long as we interject an albuminuria into our thinking we will be in imminent risk of sacrificing eyes. There is but one remedy that will cure the disease—prompt emptying of the uterus. But if there is no albuminuria, and we believe this to be an essential pathologic factor, we will miss our only opportunity to save vision, and subject the patient to the risks of a profound toxemia, already evidencing its presence in a most dangerous form.

3. *Loss of central vision or some portion of visual field, without retinal lesion.* In 1902,[4] I reported a case, the fields of which are here reproduced (Figs. 1 and 2). Her history is given here as Case 1. At the time I was able to find only one such case reported in medical literature, but another has since been found,[5] and it is more than possible that there are others, under one name or another.

CASE 1.—Patient was 33 years of age, in her first confinement. From the sixth month there had been traces of albumin, and careful watch had been kept. Her pregnancy was closed abruptly toward the end of the ninth month by instrumental delivery, after a single convulsion. Recovery was without incident, except that for four days she had transient visual disturbances, and then, with an atrocious headache, she suddenly lost the left field of vision. This was in September, 1901, and the loss has been permanent. Dr. Whitridge Williams recently furnished me with the following data concerning the urine. Its importance was not duly appreciated by me when the original report was made: "For the week prior to the eclampsia the daily amount of urine varied from 43 to 64 ounces, while the albumin and urea content varied from 0.5 to 1.5 grams and 7 to 10.5 grams, respectively. For the week following the eclampsia the quantity of urine varied from 33 to 65 ounces, the albumin occurred only in traces, while the urea content varied from 15 to 21 grams per day." The significant element is diminished output of urea.

CASE 2.—In this case the fields were taken in May, 1903, and again in March, 1908 (Figs. 3, 4, 5 and 6). Central vision then, as now, was 20/20. The papilla now is slightly pale (?). The following history was furnished by Dr. Williams: "The patient is a well-nourished woman, 37 years of age. Her fourth pregnancy began March 16, 1902. In July she complained of some headache and diminished urinary output. At this time the daily quantity of urine was 29 ounces, which contained no albumin and only 10 grams of urea. She was immediately put on a milk diet, and in the course of the next few days the urinary output had increased to 67 ounces, and the urea to 16 grams per day. Following this all symptoms disappeared. A 24-hour specimen, seen December 12, contained no albumin and 20 grams of urea. The patient went into labor on Jan. 1, 1903, and had an easy spontaneous delivery after eight hours of labor pains. The child was normal and weighed 7½ pounds.

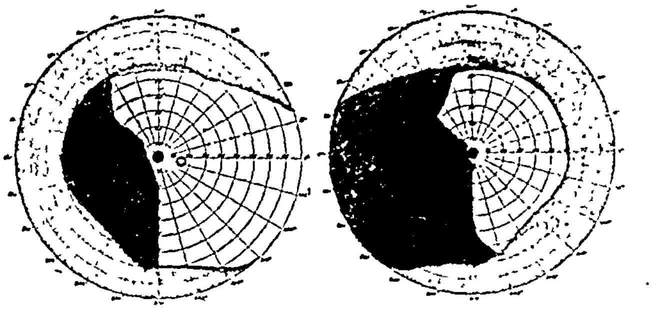

Figure 1. Figure 2.

Figs. 1 and 2.—Case 1. Fields showing loss of a portion of visual field without retinal lesion.

"The third day after labor the patient began to complain of flashes of light in her right eye, and the next day of intense neuralgic pains, particularly on the right side of the head. (The defect in the visual field occurred two or three days later.) January 13 there was a feeling of numbness on the left side. Closer examination showed a complete hemianesthesia. At the same time the muscular forces were considerably diminished as compared with those of the opposite side. On the seventh day of the puerperium the urine was negative, but on the thirteenth day it contained a trace of albumin, but no casts. A 24-hour specimen on the nineteenth day amounted to 50 ounces, and contained 42 grams of urea and a marked trace of albumin, with a few casts." Blood examination showed 4,248,000 red cells, 11,500 white cells, hemoglobin 50 per cent.

She was put on iron and made a complete recovery, except for the hemianopsia and nervous symptoms on the left side.

[4] Proc. Am. Ophthal. Soc.

[5] Brit. Med. Jour., Sept. 30, 1893.

There is still, five years later, marked impairment of sensation in the left hand and diminished muscular force, as compared with the right hand.

Dr. H. M. Thomas saw this lady in 1903, and I append a report he made in 1905: "She has, two years after the attack, marked sensory disturbance over the whole left side. Touch is perceived nearly normally, but painful stimuli with the point of a pin are not felt as sharp pricks, but at times are painful. There is marked disturbance in the perception of hot and cold stimuli. Heat is usually not perceived at all, and cold is only felt as pain and not as cold. Muscular sense is somewhat disturbed in the hand, and there is a complete loss of the stereognostic power. There is also some ataxia in the movements of the left hand. The symptoms, I believe, are the result of softening in the posterior part of the internal capsule and the region just posterior to it, probably due to a thrombosis of the posterior cerebral artery."

Case 3.—The patient had had five miscarriages, but was delivered of a full-term dead child Sept. 26, 1906. The history suggests syphilis. Her physician being dead, no particulars of gestation, etc., are obtainable. However, she had never noticed any visual defect until she was up after this confinement. Then she found herself running into chairs, etc., on the right side, and consulted Dr. J. J. Carroll, of Baltimore, who found normal central vision and the fields shown in Figures 7 and 8. She was in excellent health.

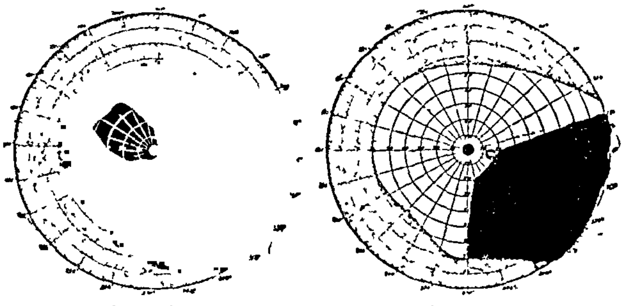

Figure 9. Figure 10

Fig. 9.—Knaggs' case. Visual field taken just before abortion occurred.

Fig. 10.—Knaggs' case. Visual field taken eleven months after abortion.

As stated, when I reported my first case in 1902, I found but one case on record, and this showed temporary right hemianopsia. F. Pick, who investigated the case, thought the visual disturbance resulted from a toxic paralysis of the central tracts of the optic nerve, with more marked involvement of one hemisphere.

R. Lawford Knaggs[5] reported the case of a woman, 40 years old, who for eight years had been blind in the left eye. The blindness was first noticed after confinement. Though not stated in the report, it is evident that she was pregnant when she applied for refraction correction for the right eye. In the course of six weeks vision failed, while the field, taken before abortion, is shown in Figure 9. There was no albuminuria. Eleven months after abortion central vision was normal, and the field showed loss of vision in the right lower quadrant (Fig. 10). The reporter thought the case one of reflex amblyopia, and quotes this explanation from Mr. Priestly Smith, "A peripheral stimulus acting through the sympathetic nerve leads to a vasomotor effect within the eye, and the defects of sight are produced through the medium of the vessels of the capillary layer of the chorioid. . . . The amblyopia is due to the impaired nutrition of the rods and cones." Mr. Knaggs recognizes that the permanent loss of a field quadrant is against this explanation, but attributes it to commencing atrophy. It is noteworthy that in the discussion E. F. Drake Brockman took exception to a reflex explanation, and hinted strongly at what we now term toxemia, with resulting hemorrhage or thrombosis. He calls it "the altered character of the blood."

J. Herbert Fisher[6] reviews several cases of what he terms "Obstetric Neuritis." reported by Dr. H. G. Turney.[7] Fisher adds a case of paralysis of one pupil, occurring during pregnancy, in connection with other nerve derangement. Incidentally, he quotes Turney's criticism of Knaggs' case, Turney attributing the blindness to a retrobulbar neuritis of toxic origin.

Mention may be made, finally, of a case reported by Dr. Charles J. Kipp, of Newark.[8] The patient lost vision in the right eye after four pregnancies, in each of which there had been ocular trouble. Dr. Kipp saw her first after her third confinement. Except for a slight loss of transparency in the region of the disc the fundus was normal. Yet there was an absolute central scotoma. There was no albuminuria. In the fourth pregnancy, with reduction of vision to light perception, there was pallor of the disc, with indistinctness of outline. Later small hemorrhages appeared in the retina. The case ended in total atrophy. Dr. Kipp says that to him "it seems most probable that the pregnancies caused a disturbance in the vascular supply, a congestion at or near the apex of the orbit, and that this produced pressure on the optic nerve and its sheaths." He says that others have attributed such conditions to autointoxication.

[7] St. Thomas' Hosp. Rep., xxv.
[8] The Journal A. M. A., June 30, 1906, p. 1986.

In all these cases, I think, nephritis can be excluded. The vascular supply and reflex explanations do not seem reasonable. From what we now know of the toxemias of pregnancy, of the results of toxemia in producing edema, thrombosis, exudation and necrosis, of the frequency of involvement of the nervous system in this toxic process, it seems to me that we abandon an adequate and ready explanation when we leave this field. For instance Dr. Kipp's case, with its central scotoma in the third pregnancy, partial recovery between pregnancies, preservation of peripheral vision throughout, seems to be a typical picture of a recurrent toxemia.

These fields are worthy of more than passing notice. In some of them the entire half is obliterated. In others, where part of the affected retinal half is spared, the tendency is decidedly toward permanent involvement of the lower quadrant. I do not know why this should be. But it has, possibly, some bearing on etiology. Assuming, as I think we should, that toxemia is the basis of the lesions, the fields indicating total obliteration of a retinal half are probably the result of a necrotic process, while those showing preservation of a quadrant are more likely the result of toxic neuritis, certain fibers ultimately escaping, while others were destroyed Thrombosis, necrosis and neuritis are essential factors of deep toxemia. It is also interesting to compare Figures 3 and 5, and 4 and 6. These are taken five years apart, from the same eyes The large "dim area" in the lower nasal quadrant of Figure 3, taken in 1903, is found in the midst of a large scotoma. Figure 5 shows some preservation of this seeing spot. Figure 4 shows that in 1903 there was a scotoma in the upper temporal quadrant, and five years later (Fig. 6) this has broken through and joined the obliterated lower temporal quadrant.

The last ocular complication of pregnancy of which I shall speak is a hemorrhagic, exudative retinitis, and does not suggest the type known as albuminuric I have seen only two such cases, and these within the past four weeks. I have not had time to make as complete a study of the literature as I should like, and hope at a later period to present the cases in a more thorough manner. However, the little research I have been able to make justifies classifying them as complications of pregnancy. Enough has been found to prove that others have observed this form of neuroretinitis during pregnancy.

There is a brief review[9] of an article by Paul Bar[10] on the poly- and mono-neurites of pregnancy. He cites two cases, one a young woman of 22, who lost both eyes in successive pregnancies from neuroretinitis. In this case there was albuminuria. In a second case, dimness of vision had been experienced toward the close of a first pregnancy, but little attention was paid to it. Later, Panas diagnosed optic neuritis. A second pregnancy destroyed both eyes. No mention is made of the urinary examination in this review, but Pujo,[11] states that the second case did not present symptoms of kidney involvement. Groenouw[12] says: "But retinal diseases, and hemorrhages in the retina in particular, also occur in the pregnant woman whose urine is free from sugar and albumin and who has no cardiac disease. Te-Mais reports on four such cases, of which three were completely cured after delivery. In the fourth case, hemorrhages of the conjunctiva appeared in the third month of pregnancy, and two months later in the retina."

Pujo studied the neurites of pregnancy thoroughly and goes over some of the cases mentioned in this paper. He concludes that the underlying cause is a toxemia of unknown nature, and excludes the kidney. The renal lesions, when present, he thinks secondary.

With this brief review of published cases, which seems sufficient to establish the existence of a pregnancy-neuroretinitis, I want to give clinical notes of the two cases recently observed, with special reference to the methods of diagnosing their toxic origin.

CASE 4 —*History.*—Feb. 20, 1908, I was consulted by a lady, 35 years of age, from the South, for blindness of the left eye. She was the mother of five healthy children. In November, 1907, when she thought herself pregnant, she had, from some cause which could not be satisfactorily determined, a hemorrhage, which was diagnosed as a miscarriage. She made a prompt recovery. The December menstrual period was shorter than normal, and that in January was missed. Her own conclusion was that she had become pregnant shortly after her menstruation in the first week of December, and the usual appearance of morning sickness confirmed her opinion. In all her previous pregnancies she had been unusually well, but in this she had not felt well, with inclination to avoid exertion, etc. As nearly as she could place the date, her first eye symptoms had appeared on January 8, when she noticed that the lower field of vision was obliterated. She was sure that this was confined to the left eye. In a day or two this cleared up, but after an equal interval she became conscious that the left eye saw poorly, and soon sight was lost altogether. She consulted a local oculist, who correctly diagnosed neuroretinitis. Mercurial treatment had been without avail. The right eye was normal.

Examination—I found extensive retinitis, with hemorrhages and large exudates over the entire fundus. There was also considerable swelling of the papilla. The veins were tortuous, thrombosed, broken in places, and there was no difficulty in determining that a venous thrombosis was at the bottom of the neuroretinitis Syphilis was absolutely excluded. There was no reason to think that brain tumor or intracranial inflammation was the cause. Yet I felt that the salvation of the right eye, if possible at all, demanded discovery of the underlying cause of the thrombosis In this connection I recalled Williams' work on toxemic vomiting of pregnancy.

Secondary results of the toxemia, which Williams claimed produced this condition, were found in the central nervous system, and I wondered if it were possible that, without the stage and symptoms of this sort of vomiting, serious nerve lesion might exist. I sent the patient to the University of Maryland Hospital for examination. Dr. Bull, of New York, to whom I submitted the history, agreed that this was the most promising line for investigation. While the urinary examinations were in progress, with the aid of Dr. Friedenwald, who saw the case with me, the literature was searched with the results already outlined.

The line of investigation may be best given by quoting from a paper on the Toxemic Vomiting of Pregnancy by Williams.[13] He first divides the subject into three varieties—neurotic, reflex and pernicious vomiting. The neurotic is often hysterical and when correctly diagnosticated can be controlled by suggestion and various simple means. Reflex vomiting is due to some malposition or other lesion connected with the pelvic viscera, and is subject to amelioration, when the toxic variety is excluded. But physical examination, to determine a reflex origin, chemical, to decide toxic origin, are needed before the neurotic variety can be accepted as the diagnosis. He says: "The urine, while diminished in amount as the result of scanty intake of fluids, does not contain albumin or casts until shortly before death, and may apparently present a normal amount of urea, as determined by the Doremus method, so that its casual examination gives no clue to the gravity of the condition. In reality, on the other hand, more detailed chemical examination at an early period reveals changes which are indicative of a profoundly altered metabolism. These consist of a decided decrease in the amount of nitrogen excreted as urea and a marked increase in the amount put out as ammonia. Accordingly, while the total nitrogen output may be practically normal, the percentage of nitrogen eliminated as ammonia is greatly increased, and this so-called ammonia coefficient, instead of being 4 or 5 per cent. as in normal pregnancy, may rise to 20, 30 or 40 per cent. . . . In my experience, if the latter (i. e., the ammonia coefficient) exceeds 10 per cent., the diagnosis of toxemic vomiting should be made, and the pregnancy immediately terminated, as there is no likelihood that the process can be checked by therapeutic measures, if it once leads to the production of the characteristic hepatic lesions."

[11] Des Nevrites Gravidiques Par Thes, 1905.

[12] Graefe Saemisch, p 184

[13] Am. Jour. Med Sciences, September, 1906.

The urine of my patient was subjected to such examination. The daily output was measured, tests for albumin, sugar and casts were made daily, and the urea and ammonia estimated quantitatively. At no time was there a trace of albumin, or sugar, and once the examiner, Dr. Adler, of the University staff, found, as he thought, a few hyaline casts. For the first three days the output was only 21, 19 and 23 ounces. Forced intake of water made very little alteration. The total urea output during these days, from February 22 to 29, varied from 4.7 to 5.5 grams, while the ammonia coefficient was persistently 14 to 15 per cent. In a word, urinalysis gave exactly what Williams had described as the diagnostic basis of pernicious vomiting. Yet there was very little nausea and no vomiting. But there was a destructive neuroretinitis, dependent on venous thrombosis, and thrombosis is a recognized result of *pregnancy* toxemia.

I had little *hope of improving* the left eye, but, after consultation with Dr. Friedenwald and Dr. L. M. Allen, I advised premature delivery as the best method of safeguarding the right eye. This was accomplished by Dr. Allen on February 29. Recovery was uneventful. Dr. Allen thought the fetus indicated a pregnancy of at least three and a half months, which throws some doubt on the supposed miscarriage in November.

There was on March 5 a urinary output of 80 ounces, with 13.75 grams of urea. Since then the daily output has not fallen below 93 ounces per day, with excretion of urea varying from 7 to 13 drams. This is still below normal, but three examinations of the ammonia coefficient show 8.3 per cent., 5.6 per cent. and 6.1 per cent. The patient has improved generally, and it is worthy of note that from having in the left eye no light perception or pupillary reaction before delivery, both are now present in certain parts of the field. Incidentally, I may add that when I dilated the left pupil for ophthalmoscopic direct examination I found at the foveal region numerous spots which I would not have hesitated to attribute to albuminuria, but at *no time* was *it* present.

CASE 5.—*The patient* was 22 years of age, in her second pregnancy. I saw her through the courtesy of Dr. Williams. She was admitted to Johns Hopkins Hospital February 5. The history shows persistent vomiting from February 5 to 17. Rectal nourishment was employed. Slight jaundice on February 16. On the 7th the ammonia coefficient was 36 per cent. On the 10th it was 20 per cent., at that time still more than double the amount on which a diagnosis of pernicious vomiting could be made. I do not know why Dr. Williams did not operate then, but he postponed doing so until the 17th. On the 16th the ammonia coefficient reached 40 per cent., and the next day the uterus was emptied. Ammonia output continued high, and the patient was intensely septic for several days. The ammonia output fell steadily, reaching 11 per cent. on March 9.

The day of first involvement of the eyes is not given, but on February 28 it is stated that the patient "could just barely count fingers when the eyes were worst." On March 2 Dr. R. L. Randolph found hemorrhagic neuroretinitis and large hemorrhages in both eyes, especially in the left eye. Exudates were scattered throughout the retinæ. On March 7 Dr. H. M. Thomas found definite symptoms of multiple neuritis, into which I need not enter for present purposes. Life was almost despaired of, but the woman has survived, and when I saw her on March 10 she seemed to have good promise of preserving both life and vision. The exudates were nearly absorbed, and so were the retinal hemorrhages. The nerves and retinæ showed no special abnormality, and there was good pupillary reaction. She saw objects in the yard and counted fingers at ten feet.

SUMMARY.

Apart from the various nervous symptoms incidental to pregnancy, which often affect the eye functions, there are four serious ocular manifestations seen more or less frequently during pregnancy or after parturition. These are: (1) The so-called uremic blindness, which is usually seen in connection with eclampsia. (2) What has always been termed the albuminuric retinitis of pregnancy. These are the most common complications. Rarer forms are (3) loss of central or peripheral vision, due, so far as symptoms point, to a retrobulbar neuritis, and (4), a form of neuroretinitis, not essentially suggestive of the albuminuric type, but showing numerous retinal exudates and hemorrhages. The clinical symptoms of these conditions are reviewed, and the classes are studied from the standpoint of recent pathological investigations in the obstetrical field. There is, in view of these investigations, doubt as to whether the term uremic should be applied to the blindness occurring in connection with puerperal eclampsia. The same is true regarding the renal origin of what is termed the albuminuric retinitis of pregnancy. There is good reason to think that both the renal and ocular complications are manifestations of the same process—a toxemia. The basis for this is set forth in the paper.

The third and fourth varieties of ocular complications of pregnancy are also, doubtless, the results of pregnancy toxemia, a toxic neuritis or toxic thrombosis probably being the active factor in causation.

DISCUSSION.

DR. CHARLES STEDMAN BULL, New York, said that modern pathology now taught that a number of ocular conditions, such as the amblyopia, occurring from excessive hemorrhage, or the sudden lighting up of latent syphilitic lesions, hitherto attributed to the pregnant state, were not due directly to pregnancy as a cause, but rather to the liability to disease induced by the lessening of the patient's powers of resistance. In certain other ocular conditions occasionally encountered in the pregnant woman, of serious prognostic significance both to vision and to life, Dr. Bull said that recent pathologic investigations made the relation of cause and effect practically certain. He believed it to be still an open question whether the so-called uremic amaurosis, or sudden and complete blindness without opthalmoscopic lesion, usually confined to eclamptic cases, was really uremic and actually dependent on derangement of organic kidney structure and function.

In the hemorrhages, and the exudative and degenerative changes in the retina occurring in connection with albuminuria.. designated as the albuminuric retinitis of pregnancy, Dr. Bull said, the prognosis as to the vision and the life of the patient depended on the duration of gestation. By the induction of premature labor a better prognosis as to the ultimate vision might be given. With the forced termination of pregnancy, the inflammatory process in the retina would subside and good vision might be restored, provided the inflammatory process had not lasted long enough to cause the secondary degenerative changes in the retina. In the retinitis of pregnancy, he said, the loss of vision appeared slowly and occurred chiefly in primiparæ and in the latter half of pregnancy. There was no contraction of the visual field, either for form or color. In subsequent pregnancies mild recurrences might be the rule.

Retinitis gravidarum, so-called, Dr. Bull said, appeared in the "pregnancy kidney" in from 1 to 20 per cent. of the cases. Unless labor were not induced, the majority of these patients, if they lived, would be permanently blind; and this persistent loss of vision, he said, pointed to the existence of some complication, such as detachment of the retina or atrophy of the optic nerve. Modern pathologists did not regard the kidney as the only pathway from the uterus to the eye. In fact, from the teachings of recent pathology, it seemed improbable that pregnancy could cause a real nephritis. Dr. Bull said that the kidney in pregnancy might be affected by lesions but they seemed to stop short of actual nephritis. It was a lesion of the renal epithelium which underwent a fatty degeneration. The "pregnancy kidney" should be regarded as a mild product of toxemia. The eclampsia, the nausea and vomiting, and the sudden partial or complete blindness, he said, must all be regarded as the results of an unknown toxic substance circulating in the blood, and not of the kidney lesion. It had been found that in these cases the liver was far more likely to be affected than the kidneys. Such a toxic substance might easily affect the optic centers also. He said that it was, therefore, incorrect and unscientific to speak of the albuminuric retinitis of pregnancy, for it did not exist unless the kidneys had previously showed the existence of interstitial nephritis.

So long as the blindness or retinitis of pregnancy was regarded as always associated with albuminuria and interstitial nephritis, doctors would run the risk of sacrificing eyes by not insisting on the induction of premature labor.

Dr. Bull added that if to regard a toxemia as the basis of all the lesions shown in the charts accompanying Dr. Woods' paper, Dr. Woods was correct in his explanation of them. For instance, when the chart showed a total obliteration of half of the field, the lesion was probably a thrombotic process. When the chart showed the preservation of a quadrant, the case was probably one of toxic neuritis of the optic nerve, certain fibers ultimately escaping, while others were destroyed.

Dr. W. C. Posey, Philadelphia, referred to a paper written by him in conjunction with Dr. John C. Hirst, of Philadelphia, entitled "The Importance of an Ocular Examination in Pregnant Women Manifesting Constitutional Signs of Toxemia," and published in The Journal March 14, 1908, l, 865-868, which described certain ocular lesions which might arise in pregnancy as a consequence of a toxemia other than albuminuria. It was stated that this, a typical and often obscure form of toxemia, manifested itself in early pregnancy by pernicious vomiting, later in persistent headache, failing vision, muscæ volitantes, epigastric pain and restlessness. Repeated examinations of the urine for albumin being negative, Dr. Posey said the obstetrician was thrown off his guard, and viewed the symptoms as local and of no particular import until convulsions occurred. He cited a case in which the patient, a young primipara, developed dimness of vision in the fourteenth week of gestation, an aching fulness in the back of the head having been present some weeks previously. The ophthalmoscope revealed pronounced neuroretinitis in both eyes, the blood vessels being full and tortuous, and a few small rounded fluffy lymph extravasations were found in the region of the disc. There were no hemorrhages. The urine was free from albumin. Active eliminative treatment was essayed, but the general and local signs of toxemia disappeared only after abortion had been successfully induced.

Dr. Posey agreed with Dr. Woods that a toxemia other than that of albuminuria might provoke ocular changes during pregnancy. The importance of an ocular examination in all doubtful cases, he said, could not be overestimated, as the detection of changes in the eye-grounds, even without the presence of albumin in the urine, should lead to the adoption of a line of treatment which might be the means of saving the life of the patient.

Dr. Casey A. Wood, Chicago, remarked that Dr. Woods had very properly passed lightly over one of the exceptionally rare sequelæ of pregnancy, namely, that form of metastatic panophthalmitis described by Hirschberg many years ago. Dr. Wood then read a report of a case of this septicemia which he had had. He added that the patient recovered as far as the general condition was concerned, and that the case differed from the great majority of cases published by Hirschberg and others, in the facts that the patient survived, and that the condition was bilateral.

Dr. E. C. Ellett, Memphis, Tenn., mentioned two cases bearing on some of the points made by Dr. Woods. He said that in November, 1907, he had been asked to see a patient aged 35, the mother of three children. In each of the two first pregnancies she had suffered with a neuritis of the branches of the brachial plexus and toothache. She had had several sound teeth extracted for relief of the latter symptoms, without effect. Relief followed delivery. She had been delivered of a third child two weeks before Dr. Ellett saw her. In the early months of this pregnancy she again suffered from brachial neuritis, which disappeared. The urine was last examined two weeks before confinement, was of normal specific gravity, and contained no albumin. On the day of the confinement she was seen at 8 o'clock by the physician, and complained of reduction of vision to perception of light. She was then in labor. The abdomen was unusually distended, so that no fetal outlines could be distinguished. Delivery at about 10 o'clock was followed by the discharge of a considerable quantity of dark blood and clots, but no active bleeding. For the first twenty-four hours there was absolute suppression of urine. In the next twenty-four hours not more than an ounce of urine was passed, and this was highly albuminous. After this the secretion increased, and the albumin lessened. Two weeks after confinement Dr. Ellett found vision practically normal, fields normal, eye-grounds normal except as to color, which was affected by the intense anemia from which the patient still suffered. The urine was normal in quantity and specific gravity and contained no albumin. It was not examined otherwise or microscopically at any time. In February, 1908, it was proposed to do a curettage for an endometritis. Chloroform was administered, and the patient died on the table from the anesthetic before the operation was begun.

The second patient was seen in 1902. Three months previous to Dr. Ellett's examination she complained of a sudden blurring of vision, worse in the left eye. Nine years previously, during a pregnancy and for six months after delivery, she had had uremic symptoms and impaired vision. She had recently been told by a very competent abdominal surgeon, who had seen her at intervals during this time, that she was well of her kidney trouble. She had postneuritic atrophy of both optic nerves, with slight impairment of central vision, and while under Dr. Ellett's observation the fields, at first normal, in two years became markedly hemoptic. The urinalysis showed specific gravity 1.003, no albumin, no casts; all the organs were normal. The patient took strychnin at Dr. Ellett's advice and with the consent of a colleague, almost all this time. In April, 1905, she saw Dr. Ellett's colleague on a Saturday, and he advised stopping the strychnin. She died suddenly the following Tuesday.

Dr. Ellett said that the evidences of toxemia were plain in both of these cases. In case one, the brachial neuritis could not so readily be explained on any other ground. *In both cases* he believed that an enfeebled and degenerate heart muscle must have resulted from the toxemia, and that this muscle suddenly gave way, in one case under the depressing *influence* of chloroform, and in the other when the accustomed stimulant was withdrawn.

Dr. Arnold Knapp, New York, said that some of Dr. Woods' cases corresponded to the group he had reported last year before the American Ophthalmological Society, in which there was an optic neuritic atrophy. This was associated with the symptoms now taken to mean toxemia. Further manifestations of this condition were shown in the analysis of the urine in which a diminution of the nitrogenous element, a disturbance of the nitrogen ratio, was found. Dr. Knapp remarked that the findings in the urine offered a more promising field than in the case on which Dr. de Schweinitz had just reported. As to the form, neuroretinitis with hemorrhages, it seemed to Dr. Knapp that the cases which he observed were associated with sepsis and that it was not possible to say that the condition was not due to the septic state, especially as, according to the obstetricians the toxemia predisposed to sepsis and the association of the two conditions seemed not unusual

DR HARRY FRIEDENWALD, Baltimore, said that he had had an opportunity of observing several patients who had recovered from eclampsia but were blind for some hours or days after delivery In one of them the recovery of vision was so interesting that he thought it worthy of mention in this discussion He remarked that it was generally assumed that the visual impairment in eclampsia was due to the toxic effects upon the cerebrum In this patient the vision gradually returned, but there was at first a very marked central scotoma, it was the periphery of the field of vision in both eyes that recovered first and only after several days did central vision improve and gradually return to normal Dr Friedenwald assumed that in this case the toxic effect was on the optic nerve and not on the cerebrum

DR ROBERT RANDOLPH, Baltimore, agreed that the proper course to pursue in the treatment of this class of cases was to induce premature labor where it was evident that the integrity of the retina is in danger He felt that one would probably be justified in believing that the retinal changes of pregnancy were due to the toxemia of pregnancy and not to renal disease, if in the majority of cases of retinitis observed in pregnancy no albumin were found in the urine, but such, he said, was certainly not the case Ten years ago he reported five cases of albuminuric retinitis in pregnancy, all with marked ophthalmoscopic pictures, all had albumin in the urine and in two the urine was loaded with albumin In going over the literature at that time Dr Randolph noted that all who reported on cases of this character had found more or less albumin in the urine Since then he had seen two cases of retinitis albuminurica of pregnancy and in both cases examination of the urine revealed albumin and casts To his mind there was no retinal change so infallibly suggestive as the picture called albuminuric retinitis, with its flaky superficially situated specks, not necessarily arranged in the classic way in the macular region, but distributed indifferently about the retina and impressing the observer by their evidently superficial location He said that his own anatomic observations placed these changes for the greater part in the nerve fiber layer, the ganglion cell layer and internal granular layer The toxemia of pregnancy might be responsible for the eclampsia, but it should be remembered that this question of the pathogenesis of eclampsia had always been and still was a debatable one and, he said, according to Hirst at least three fourths of eclampsia cases had albuminuria Dr. Randolph remarked that recent observations had rather lessened the importance of renal disease as a cause of eclampsia, yet in by far the majority of cases of eclampsia there was demonstrable proof of renal disease This being the case one would have no more right to deny the agency of the kidney trouble in causing the retinitis than to deny the origin of the retinitis in a non pregnant individual who presented the usual signs and symptoms of a chronic interstitial nephritis Dr Randolph felt that he hardly needed to call attention to the necessity of making repeated examinations of the urine before deciding to accept or reject the diagnosis of renal retinitis Lucien Howe years ago reported a case where the typical picture of albuminuric retinitis was seen and it was not until three months later that albumin and casts were found in the urine This would suggest the possibility of this form of retinitis being occasionally a prealbuminuric sign of renal disease

Dr Randolph said that a month ago he had seen a woman whose right retina was covered with a number of soft, white, superficially located specks, and he had felt almost instinctively that he was dealing with a kidney trouble Yet examination of the urine at that time failed to reveal either albumin or casts Two weeks ago the patient's family physician, to whom Dr Randolph referred her, reported that nothing abnormal had been disclosed by repeated examinations till the last three each of which showed casts and albumin which with a high blood pressure, suggested the presence of a contracted kidney Dr Randolph remarked that Dr Woods had called attention to the fact that Dr James Bordley, Jr, had observed the characteristic feature of albuminuric retinitis in sixteen cases of brain tumor in which no albumin was found in the urine He said that the occurrence of this condition was well known but care should be exercised in drawing conclusion until the possible renal involvement had been completely excluded. Dr Randolph had recently examined two cases of brain tumor in the Johns Hopkins Hospital in both of which there were choked discs and the so called albuminuric retinitis, but in both of these cases casts and albumin were found in the urine

DR MARCUS FEINGOLD, New Orleans, said that if this classification of retinitis in pregnancy as being not the effect of the albuminuria but of the toxemia were accepted as correct, then the question would always arise in the mind of the practitioner, what to do when confronted with a case of retinitis in a patient never before examined? Could it be called a case of retinitis due only to the toxemia or a case of retinitis in a woman who had previously had nephritis? The question he said, was of great importance from the standpoint of therapeutics, in a case due to toxemia it was the physician's duty to interrupt pregnancy at once so as to stop the toxemia, in a case due to albuminuria proper the indication was not as plain he believed, because obstetricians as a rule would not perform an abortion unless the nephritis produced eclamptic symptoms Dr Feingold believed that there was justification for the more radical measures in every case He cited the case of a patient who during pregnancy became suddenly blind She consulted Dr Feingold some months after confinement and then presented a typical post neuritic atrophy with remnants of hemorrhage in the eyes Whether this was a case of albuminuric retinitis, or retinitis in pregnancy from toxemia was difficult to decide Dr Feingold advised in such a case the performance of an abortion Another patient consulted Dr Feingold for headaches He found an error of refraction but also a condition of retinitis of pregnancy He advised abortion, it was performed, and the patient recovered

DR HIRAM WOODS, Baltimore, replied to the problem outlined by the two last speakers, namely, how the diagnosis of toxic or renal origin was to be made in a case of exudative retinitis in pregnancy, or in a case of neuroretinitis without the spots thought characteristic of renal origin by saying that it was to be made by urinalysis along the lines suggested in Dr de Schweinitz' paper of the same day, and illustrated in two of the cases narrated in Dr Woods' own paper If the contention of Williams and other obstetricians was correct—that liver changes were responsible for a general toxemia capable of affecting the kidneys and nervous system alike that both were direct results of the toxic substance, and that the kidneys were not the pathway to the nervous system—then Dr Woods said the diagnosis of this toxemia became a matter of grave importance Further if the contention was correct that the urea output was so altered as to produce an excess of elimination of urea in the form of ammonia—in other words an increase in the ammonia coefficient—then there was a definite chemical line of investigation

Dr Randolph had said that in the cases of eclamptic blindness which had come under his observation, there had usually been albuminuria The point Dr Woods wished to make was that, even so, physicians were not justified in attributing this blindness solely to uremic poisoning as the text books did This form of blindness he said, was observed in the uremic convulsions of chronic nephritis, and accompanied the usual symptoms of defective elimination It was, moreover a serious symptom in the course of chronic kidney lesion but when occurring in connection with puerperal convulsions, it was but one part of a symptom complex of which convulsions were another part Owing to this frequent association with albuminuria the whole eclamptic phenomenon had been laid at the door of albuminuria Clinical observations however, had often shown the absence of albuminuria, and the subsequent course of the puerperal cases usually negatived the hypothesis of renal origin, at least the course was usually different from that in the true nephritic Again observations at autopsy showed insignificant renal changes often and more constant characteristic liver lesions These facts had led Edgar and other obstetricians away from the renal origin of eclampsia, and made them attribute the whole phenomenon to some poison of unknown nature, but, according to Edgar, not uremic. Why, then, Dr. Woods asked, should ophthalmologists persist in picking out one symptom of this phenomenon as certainly uremic, especially when the obstetricians had taught that albuminuria could also be a secondary result of toxemia?

THE RELATION OF OCULAR AND CARDIOVASCULAR DISEASE.*

MELVILLE BLACK, M.D.
Professor of Ophthalmology, Denver and Gross School of Medicine.
DENVER.

This subject, I am sure, is not new to you, but since we are learning more about it every day, a few of my personal ideas and findings may prove of interest. The estimation of blood pressure has brought about a more comprehensive knowledge of cardiovascular disease. The remote disturbances which follow this important condition, and the etiologic factors which gradually lead up to it, are now receiving much attention. It is a well-recognized fact that a man may be on "his last legs," so to speak, from cardiovascular changes, and yet feel no serious bodily discomfort. He may have, therefore, no urgent reason for consulting his physician, but may have reason to consult his oculist, and we should constantly be on the lookout for ocular evidences of these vascular changes.

The recognition of these early changes in the retinal circulation may enable us to give many years of life to a considerable number of our patients. The "optometrist" will always be incompetent to recognize these danger signals in the eye, and it is one more urgent reason why he should not be licensed to practice his would-be profession. While the ophthalmologist keeps pace with the body of the medical profession in its new discoveries, the technical knowledge and the equipment required to make a thorough examination of the urine, the blood, and an all-round physical examination of the individual goes beyond his province. He has served a most useful purpose, however, in having recognized the ocular signs which warrant such a physical examination, and has done his duty by seeing that the patient had such an examination made.

It is no disparagement to the general practitioner to say that he also is incompetent to make this examination. It has been my policy to refer such a patient to some one capable of making this all-round examination, and then send him to his physician with the full report of our findings. I must confess that my efforts have been several times thwarted by the family physician making light of the entire matter. He thumps the patient a little, listens to his heart through a few intervening thicknesses of clothing and directs him to "go about his business." A dilated heart can only be mapped out by the most painstaking deep percussion. The presence of a low blood pressure, polycythemia, and dilated, tortuous retinal veins, uricacidemia and indicanuria all point to a clear diagnosis of general venous stasis, which tends not only to shorten life, but also opens the way to many physical mishaps before the end comes. The cases I am about to report show how these mishaps may affect the eyes.

I believe it is generally accepted that high arterial pressure is a common cause of renal and arterial degeneration. It has been my observation that in chronic interstitial nephritis, with high blood pressure, where the retina is involved, the reduction of the blood pressure is all important, and that thereby several years can be added to the life of the individual (Cases 11, 12 and 13). Case 11 shows not only how life was prolonged when the patient was on the verge of uremic convulsions, but how useful vision was preserved until her death.

I have been especially impressed with the frequency with which general venous stasis was found present in many cases of degenerative ocular changes (Cases 1, 2, 3, 4, 5, 6, 7 and 9). Several of these patients I never saw again; consequently I am unable to report on the results of treatment, but they serve to show the relationship, as mentioned. If the vascular changes were not instrumental in causation, then the etiology was certainly indeterminable. At our altitude of one mile above sea level we undoubtedly see more cases of heart dilatation and venous stasis than do those living at lower levels. How much greater the relative proportion is I do not know.

It is now a recognized fact that four-fifths of the heart lesions are muscular and that one-fifth are valvular. The influence which impaired circulation, caused from a weakened heart, has on the economy is now being studied extensively. The ophthalmologist is in a position to see some of the very direct results of muscular heart lesions; he should, therefore, be thoroughly alive to the importance of this subject.

CASE 1.—*Retinal Hemorrhage, Due to Dilated Heart, General Venous Stasis and Polycythemia.*—Mrs. J. G. M., age 37, Aug. 8, 1907. Has been feeling well physically, with the exception of some shortness of breath on exertion. Two months ago she noticed a blurring of vision in the left eye, which has undergone no improvement.

Status Præsens.—The retina of O. S. is highly engorged. The veins are tortuous and greatly distended. Flame-like hemorrhages are present everywhere along the veins. The nerve head is red, outlines indistinct and somewhat swollen above.

The appearance of the fundus of O. D. is practically normal. The veins are somewhat larger than they should be. O. D. V.=20/20; O. S. V.=2/200. She was referred to Dr. E. C. Hill for physical examination, who reports as follows: Pulse, 92, sitting; 110, standing. Heart, one-half inch to left of nipple and one-half inch to right of sternum. Blood pressure, 105; 107 after exertion. Hemoglobin, 95 per cent. Red blood cells, 7,800,000. Urine, 1,027 c.c. in twenty-four hours. With the exception of a slight excess of indican and uric acid it is normal.

Treatment.—Fifteen drops tincture of strophanthus before meals, and 1/30 gr. strychnia after meals. Diet: Not more than two and one-half pints of fluid daily. Meat once daily. No coarse vegetables, such as cabbage, corn, etc. Potatoes and bread restricted. Fruit and green vegetables freely. Generally speaking, her diet is to be very simple and she must eat sparingly. Results two months later: O. S. V.=20/30. Retinal hemorrhages all absorbed. Veins more normal in size and appearance; nerve head a little muddy. Dr. Hill finds her heart normal in size. Blood pressure, 108. This lady lives in Ohio and was seen by me while on a visit to Denver, consequently our altitude had nothing to do with the production of her venous stasis.

CASE 2.—*Optic Neuritis, Associated with Exophthalmic Goiter. Dilated Heart, General Venous Stasis and Autoinfection.*—Mrs. C. H., age 31, November, 1906. History of enlargement of the thyroid gland with some exophthalmic symptoms. The enlargement has about disappeared under electropuncture. Eyes have been paining her for two years. Has had a number of transient blind spells. Vision became permanently affected eight months ago. It has gradually been growing worse. Has not been able to read for three months.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Status Præsens.—O. D. V. = fingers at four feet. O. S. V. = fingers at six inches. Left pupil larger than right, reactions for light and accommodation slow. Fields: Not enough vision to take left field; the right is contracted equally in all directions to the 5 degree line. With the ophthalmoscope, the nerve head of O. D. is swollen 5 D. No retinitis. The left nerve is almost completely atrophic. She was sent to Dr. Hill for physical examination, who reports as follows: Heart dilated to one and one-eighth inches beyond sternum and two inches beyond nipple. Blood pressure, 120. Pulse, 108. Urine, great excess of uric acid and indican. Red blood cells, 4,480,000. Patient disappeared.

CASE 3.—*Retinal Hemorrhage, Associated with Polycythemia and Autointoxication.*—Mr. B. D. S., age 44, Aug. 13, 1903. Very full-blooded, florid-looking man, who is apparently somewhat over weight. Claims to have always enjoyed good health. Is a heavy eater, but has no other dissipations. About six weeks ago noticed that vision of O. D. was poor; no improvement since.

Status Præsens.—O. D. V. = 3/40. O. S. V. = 5/6. The entire macular region of the right eye presents the appearance of numerous hemorrhages, with chorioiditis. The veins are very large and tortuous, and the nerve head is red. Sent him to Dr. E. C. Hill for physical examination, who reports that his heart is about normal, but that his red blood cell count is 8,200,000; that he is passing only about one-half the normal amount of urine in twenty-four hours, which contains a considerable excess of indican, and three times the normal amount of earthy phosphates. He advises that he drink twice as much water as he is now drinking, and that his diet be of the simplest form; that it be largely vegetable and that he be allowed only one full meal a day. He was given 10 gr. iodid of potassium, t. i. d., 1/32 gr. biniodid of mercury, t. i. d. In three months time his vision had improved to 5/15. The fundus shows a few scars. No new hemorrhages. I saw him last in February, 1906. He had O. D. V., 20/30. Almost no retinal signs of his former trouble. I had Dr. James Rae Arneill examine him physically for me. He found his blood pressure to be 135; hemoglobin, 105 per cent.; urine normal. A letter received from him a few days ago says the eye still remains well.

CASE 4.—*Retinal Hemorrhage, Associated with a Weak Heart and General Venous Stasis.*—Dr. J. M., age 53, Aug. 21, 1907. Has noticed a dimness of vision in lower field of right eye for ten days. He has been actively engaged in country practice for many years. Has no dissipations, unless it be in his eating. He is a hearty, rugged looking man.

Status Præsens.—The upper temporal quadrant of retina of O. D. is covered with flame-shaped hemorrhages. The veins are very full and tortuous. Nerve head congested. He was referred to Dr. E. C. Hill for physical examination, who reports as follows: Blood pressure, 99 sitting, and 107 after exertion; hemoglobin 90 per cent., red blood cell count, 5,350,000; heart is not dilated but degenerated and weak; urine 26 ounces in twenty-four hours; uric acid, one-third above normal daily maximum; no excess of indican.

Diagnosis.—Passive congestion.

Treatment.—Strychnia and hydrastinin hydrochlorid, and correction of his diet. Dec. 24, 1907, he reported that the vision in the lower nasal field is much improved. Is feeling well. Thinks blood pressure is higher than it was.

CASE 5.—*Recurring Retinal Hemorrhage, Associated with Dilated Heart, General Venous Stasis and Autointoxication.*—F. S. T., age 26, Sept. 26, 1905. Occupation, farm hand. Has always enjoyed good health. For the last three weeks he has seen a curtain hanging in front of left eye.

Status Præsens.—O. D. V. = 5/5. O. S. V. = 5/27. With the ophthalmoscope a membrane is seen lying in the anterior portion of the vitreous, which is fixed; also large floating pieces of membrane. The appearances are of a previous vitreous hemorrhage which is being absorbed. The fundus can not be seen. Sent him to Dr. E. C. Hill for physical examination, who reports: Blood tension, 165; heart normal; pulse, 88 sitting, 100 standing; hemoglobin, 90 per cent. The urine shows considerable excess of indican, uric acid and earthy phosphates.

It was decided to reduce tension somewhat by the use of a very simple diet, also to correct intestinal fermentation by giving him 10 grains of sulphocarbolate of sodium, t. i. d., and 3 grains of calomel once a week. A month later the vitreous was found almost clear and V. = 5/9. No fundus lesion could be found. He was told to continue treatment for another month and report. He was not seen again for nine months, when he came because of another vitreous hemorrhage, which had occurred six weeks previously. I found his vitreous full of floating membrane, and a retinal spot could dimly be seen below the macula. Dr. Hill went over him again and found his blood tension 115; heart, much dilated; no indicanuria. He was given 10 drops each of tincture of strophanthus and nux vomica, t. i. d.

Two months later Dr. Hill found his heart still somewhat dilated and had him continue the heart tonics. I found a little floating membrane in the vitreous, and that the spot below the macula was becoming atrophic. I did not see him again until two months later, when he came in with a corneal ulcer caused by the diplobacillus, which quickly healed under zinc. The vitreous is now perfectly clear and O. S. V. is 20/20. There are three spots of atrophic retina to be seen, a small spot just to temporal side of disc, a large one below the macula and a third some distance below the disc.

Four months later he came in saying that the right eye had been blurring for ten days. O. D. V. = 20/70; O. S. V. = 20/20. The vitreous of right eye contained floating membrane and no fundus details could be made out. Dr. Hill found the heart so dilated that the heart border was one and one-quarter inches to the right of the sternum and one-half inch to the left of the nipple in the sixth interspace. Pulse, 92 sitting, 105 standing. Blood pressure, 132; hemoglobin, 100 per cent. Marked indicanuria. In four days the vitreous had so cleared that a retinal spot could be seen on the nasal side of the disc. He was seen again three months later, when vision in each eye was found to be normal. The blood vessels of the retina have not the appearance of sclerosis. Dr. Hill found the blood pressure 145 mm., and heart almost normal in size.

Three months later he had another attack in the left eye. The vitreous was muddy, but there were no large pieces of floating membrane. Dr. Hill found his heart again badly dilated with a blood pressure of 115. This case illustrates the relation in a young man between vitreous hemorrhage and venous stasis, and how between attacks of the latter his vascular condition was comparatively normal.

CASE 6.—*Asthenopia, Associated with Retinal Venous Congestion, Heart Dilatation and General Venous Stasis.*—Mrs. M. A. H., age 35, Jan. 9, 1906. Complained of eyes watering and tiring for near work. Thinks vision is poor.

Status Præsens.—The vision of each eye is 5/7.5, with —.50 cyl., ax. 180°. Both nerve heads are congested, and the medium-sized veins are tortuous. I sent her to Dr. Hill for physical examination, who reports as follows: Amount of urine passed in twenty-four hours is 8 ounces, which contains a trace of albumin. No excess of indican nor uric acid. No casts. Blood pressure, 121. Heart very much dilated and leaking all around. The right border one inch to right of sternum. Hemoglobin, 95 per cent. Diagnosis, general venous stasis.

She was referred to her family physician for treatment. Results, unknown.

CASE 7.—*Conjunctival Edema, Associated with Heart Dilatation, General Venous Stasis and Autointoxication.*—Mrs. F. H. B., age 52, February, 1906. Eyes have been inflamed and in about the present condition for three months. Has worn glasses for three years. Has always enjoyed good health.

Status Præsens.—The eyes look very red and watery. The ocular conjunctiva is edematous and rolls up in front of the lid margins when winking. The palpebral conjunctiva does not appear to be affected. Sent her to Dr. Hill for physical examination and for bacteriologic examination of the ocular secretions, who reports as follows: A smear of the ocular secretions shows fatty degeneration of the epithelial cells, some ordinary staphylococci and proteus bacilli, but no diplobacilli. Pulse, 87 sitting, 90 standing. Heart, one and three-eighths inches beyond left nipple and one-half inch to the right of the sternum; the apical sounds were somewhat weak. Blood pressure, 121. Red cells numbered 6,200,000; hemoglobin about 95 per cent.; no excess of leucocytes. The urine shows an excess of uric acid and indican. He believes her eye trouble is partly due to uricacidemia, but mainly to stagnant circulation at this altitude. The treatment prescribed was strophanthus and nux vomica. Jan. 4, 1908, a letter from her stated that her eyes are better.

CASE 8.—*Asthenopia, Associated with Heart Dilatation, General Venous Stasis.*—Mr. G. M., age 42, April, 1907. Has been having so much pain in eyes and back of head that he has been compelled to stop work. His refraction was estimated to be + 1.50 W — 50 cyl., in each eye, with 20/20 vision. These glasses were ordered. In the macular region of each eye there were seen shimmering lines and irregular splotches of a yellowish color. The veins were greatly dilated and the arteries small. He obtained no relief from wearing the glasses. He was referred to Dr. E. C. Hill for physical examination, who found: Blood pressure, 111; right side of heart greatly dilated. Hemoglobin over 100 per cent. He was placed on appropriate heart tonics, and in the course of two weeks time his headache was relieved and he was able to return to work.

CASE 9.—*Episcleritis, Associated with Dilated Heart, General Venous Stasis and Autointoxication.*—Mrs. R. C. D., age 38, March, 1907. Her left eye has been subject to attacks of inflammation on the temporal side of the cornea. The eye becomes intensely injected over this portion of the globe, and is very tender and painful. The attack subsides in a few days and the eye becomes almost white; another attack follows in about a week or ten days. She was referred to Dr. Hill for physical examination who reports that she has a dilated heart, which is extended three-eighths of an inch to left of nipple and one-half of an inch to the right of the sternum. Pulse, 95 sitting, 106 standing. Blood pressure, 102. The urine shows a large excess of indican and uric acid. She was placed on strophanthus and sulphocarbolate of sodium and simple diet.

CASE 10.—*Retinal Hemorrhage, Associated with High Blood Pressure.*—Mrs. Henry W., age 72, Aug. 19, 1907. General habit, plethoric. Has no complaint to make physically. For three months she had had two spots before left eye and has been aware of a gradual failure of vision.

Status Prœsens.—O. D. V. = 20/20 W + 2.00. O. S. V. = 20/70 W + 1.75. With ophthalmoscope numerous hemorrhages are seen scattered throughout the retina of left eye. There are no hemorrhages in the right eye, but the blood vessels show strong evidences of sclerosis. She was referred to Dr. F. W. Kenney for physical examination, who reports as follows: Blood pressure, 240; heart normal; no kidney disease. This patient is still under observation. Her blood tension is still high.

CASE 11.—*Neuroretinitis, Associated with Chronic Interstitial Nephritis and High Arterial Tension.*—Mrs. M. B., age 45, Jan. 19, 1907. Has been suffering of late with severe diffused pain in head. Eyes so sore she can scarcely move them. Has been aware of a central blind spot in right eye for several days.

Status Prœsens.—O. D. V. = 20/40; not improved. O. S. V. = 20/20; not improved. With the ophthalmoscope a typical picture of albuminuric neuroretinitis, with hemorrhage, is seen in each eye. The condition was more advanced in her right eye. She was referred to Dr. E. C. Hill for physical examination, who found she was on the verge of uremic convulsions from chronic interstitial nephritis. Her blood pressure was 240. Active measures were taken to reduce the high blood pressure. When it came down to 200, her headache stopped. It was gradually brought down to 185 and 190. The neuroretinitis gradually improved. In two months time the retinal hemorrhages were all absorbed, but the striæ and spots of retinal degeneration, and the opaque sclerosed blood vessels were more marked than ever. Four months later there was scarcely a trace remaining of the retinal degeneration. Vision was 20/20 in each eye, with full fields. She died just a year after my first examination, and enjoyed a fair degree of comfort with good vision until the end.

CASE 12.—*Neuroretinitis, Associated with Chronic Interstitial Nephritis and High Arterial Tension.*—Mrs. J. I. G. age 50, March 27, 1905. Referred to me by an optician to have her eyes examined for glasses. Has little complaint to make about eyes or her physical condition.

Status Prœsens.—O. D. V. = 5/9:5/6 W + 75. O. S. = 1/200; not improved. With the ophthalmoscope a typical picture of albuminuric neuroretinitis was seen in each eye, which was more advanced in the left eye. Numerous retinal hemorrhages in both. She was referred to Dr. James Rae Arneill for physical examination, who reports that she has a dilated leaking heart, blood tension 260. Urine shows albumin and hyaline casts. I never saw this patient again. She felt well and could not believe that she had chronic Bright's disease. Much could have been done to prolong her life had she been willing to follow directions. As it was, I learned that she died after a few months, and that she became almost blind before her death.

CASE 13.—*Retinal Hemorrhage, Hemorrhagic Glaucoma and Optic Nerve Atrophy, Associated with Chronic Interstitial Nephritis and High Arterial Tension.*—Mr. H. L., age 60, Nov. 16, 1903. Vision has been blurred for ten days. Has always enjoyed good health. Has been a dissipated man as regards alcohol and tobacco. Has not drunk any during recent years.

Status Prœsens.—O. D. V. = 5/15. O. S. V. = 5/15. The field of O. D. is contracted temporally to the 5 degree line, the left is normal. The ophthalmoscope shows marked evidences of sclerosis of the retinal vessels in each eye. The disc of O. D. is cupped. In O. S. the nerve head is congested, the adjacent retina edematous, the veins engorged and tortuous, and numerous retinal hemorrhages occupy the inferior nasal quadrant. He was referred to Dr. Hill for physical examination, who reported as follows: Albumin, 1 2/5 per cent. by volume; hyaline, coarsely granular and disintegrated blood casts. Blood tension, 240. He was placed on a strict diet, and was given 3 grains sodium nitrite, t. i. d., and a pill composed of euonymus, aloes and belladonna.

Jan. 18, 1904.—Great loss of vision. O. D. = Fingers at two feet. O. S. = Hand movements. O. S. was inflamed. T + 1. Vitreous so hazy that fundus could not be seen. Iris sluggish and off color. Dr. Hill found the albumin in urine reduced to 1¼ per cent. by volume, and his blood tension was 215. The left eye went from bad to worse.

Diagnosis.—Hemorrhagic glaucoma. Enucleation. The vision of his right eye was now so poor that he could not see to get about alone. This was due to a scotoma which encroached on central vision and extended below temporally and nasally, about 20 degrees in each direction. He has been using eserin in oil in this eye, but I can not see that it has been of any service. It is doubtful if there has been, at any time, any increase of tension. For some months this eye remained about the same, and then the central scotoma increased until it occupied the entire temporal field. He has had numerous hemorrhages, but they have not caused hemorrhagic glaucoma as they did with his left eye. I saw him last in July, 1907. He had perception of light only, and numerous retinal hemorrhages were present. Dr. Hill estimated his blood tension several times, and found it to range from 135 to 145. He had a small amount of albumin in his urine. This patient is alive to-day because of the reduction of his blood pressure. His ocular mishaps were most unfortunate, and had he been seen a year or so sooner they might have been prevented.

The above cases serve to show how important are the ocular changes in pointing to the existence of cardiovascular disease. A greater number would needlessly prolong this paper.

DISCUSSION.

DR. LEWIS H. TAYLOR, Wilkesbarre, Pa., said that the profession was coming to recognize more and more the important fact that in certain cases treatment must be directed not to the eye but to the general system. It was hard for the oculist in the face of such conditions to say frankly: "This is a serious eye trouble but I am not competent to treat it." He need not say this if he were physician as well as oculist. Moreover, Dr. Taylor said it was not always convenient and sometimes not possible to refer patients to expert heart specialists.

Dr. Taylor said that he had had more cases of vascular trouble ending in retinal hemorrhage in the past two years, than ever before in a corresponding period in his whole practice. He related part of the history of a case of retinal hemorrhage. The patient was a strong, hearty man, aged 44 in 1884. He was then fitted with glasses and again twelve years later. In this year he had his first hemorrhage. Two years later the vision rose to 20/XXX some in XX in the patient's right eye, and this was now his better eye. Two years later another attack came and vision of the right eye fell to mere perception of waving hand. Subsequent hemorrhages occurred, ending in hemorrhagic glaucoma for which condition Dr. Taylor enucleated the right eye. The patient's remaining eye had had retinal hemorrhages some years before and was for some time the poorer eye. The patient had always had a full pulse, but soft. His diet was regulated. Fresh hemorrhages, however, occurred in the remaining eye at intervals of two and one years and a severe one in 1907. The patient had been treated by local and general blood-letting, regulation of life, and various medicines. Following the hemorrhage in the spring of 1907, he was practically blind through the greater part of the summer, but rallied and recovered a considerable amount of vision so that he was able to go about alone, but was never able to read. In February, 1908, a day of considerable excitement brought on dimness of the eye, but no hemorrhage was visible. The patient was at once put to bed and placed on treatment to lower arterial tension and on March 2 twenty-four ounces of blood were taken from the arm. The hemorrhages increased with great intensity, causing great pain and high tension which eserin, pilocarpin and dionin could not relieve. The anterior chamber was filled with blood and an iridectomy or sclerotomy was out of the question. Even the skin around the eye was affected with hemorrhages, extending down to the neck. The patient suffered along for a month longer being kept part of the time under the influence of morphia, having at times some improvement to be followed by subsequent hemorrhages. He finally agreed to an enucleation, but in the morning of the day fixed for operation the ball ruptured. After enucleation the hemorrhages continued and were not forcibly checked because of the pain, and because Dr. Taylor considered that it would be better for the patient's head to allow the hemorrhage from the orbit to continue. Oozing of blood, at times free, continued for nearly three weeks, checked finally by adrenalin externally and internally. Dr. Taylor said that the patient had now fully recovered his general health and rode out daily. This patient had been seen by Drs. Knapp, Bull, Risley and de Schweinitz and all had predicted apoplexy as a possibility. Dr. Taylor thought it surprising that the patient had not had a rupture of a blood vessel in the brain before this.

DR. GEORGE E. DE SCHWEINITZ, Philadelphia, said that Dr. Black's insistence on the point that early recognition of angiosclerotic changes might enable physicians to give many years of life to a considerable number of patients deserved to be emphasized. He said that it should also be remembered that even more important than the grosser changes were the early signs of cardiovascular disease, particularly the early signs of general arteriosclerosis, such as lesions of the arterial walls, alternate contractions and dilatations of the veins, indentation of veins by stiffened arteries, and later hemorrhagic extravasations, perivasculitis and silver-wire arteries. Dr. de Schweinitz called attention to still earlier indications, the curious corkscrew appearance of certain arterial twigs, notably those skirting the macula, the crinkled retinal vessels of Alleman's phraseology, the flattening of a vein in contact with an artery, resembling somewhat the appearance of a diminutive strap laid across a solid tube, most frequently evident in the inferior temporal retinal vessels, and the peculiar appearance of the nerve head; with its slightly dull red appearance, differing from a frank congestion precisely as the unhealthy flush of a cheek differs from the brighter color of the normal blush.

Dr. de Schweinitz said that the signs of angiosclerosis looked for by the general clinician—the condition of the pulse, the character of the heart sounds, particularly that of the first sound at the apex and of the second sound at the aortic area, the increased tidal wave on the sphygmogram, and the elevation of tension recorded by the sphygmomanometer—might result from numerous and varied conditions of the system, organic and nervous in origin, and not necessarily connected with arteriosclerosis. The ophthalmoscopic signs, suggestive or pathognomonic—in their earliest or in their latest stages—he said were certain evidences of local angiosclerosis and frequently of persisting high arterial tension, either of general arteriosclerosis or of its manifestations in special organs, and therefore ophthalmoscopic examination was one of the most ready clinical means for the early detection of important arterial changes. Dr. de Schweinitz believed the ophthalmoscope equal in value if not superior to any of the well-recognized methods of the detection of such a condition; and he thought its findings, unlike those of the sphygmogram and even the sphygmomanometer, diagnostic, if positive. No one, he added, was prepared to say that in the absence of ophthalmoscopic changes there must be absence also of arterial degenerative changes, but in the presence of the former, other things being equal, and local changes in the eye being excluded, the findings, if positive, were diagnostic.

DR. CHARLES H. WILLIAMS, Boston, wished to call attention to the necessity of a very careful ophthalmoscopic examination of these cases. He said that he had a case recently in which the pupils were small and there was general haziness of the vitreous so that it was very difficult to get a good view of the fundus. Under cocain dilatation, however, he found abundant hemorrhages in the retina and a large number of changes in the retinal vessels, some being obliterated and some reduced to small white lines. This patient was about to sail for Europe. Dr. Williams advised strongly against it and wrote a letter to the patient's family physician. He received an answer taking him to task for having frightened the patient.

DR. EDWARD JACKSON, Denver, illustrated the breadth of this subject and its importance to the ophthalmologist by citing the case of a man, aged 58, whose sight had been growing worse for three months, and who came with vision reduced to 4/22 and 4/12. Ophthalmoscopy showed dilatation of the veins, which were narrowed at the crossings of the arteries. Color-perception was markedly interfered with, but there was still fair perception for yellow and blue near the center of the field of vision. This patient had a blood pressure of 140 mm. Considering the condition of his veins Dr. Jackson inferred that the pressure though not absolutely low, was temporarily low for that particular individual. The patient was referred to Dr. Hill, who found marked dilatation of the heart. Here, Dr. Jackson said, was the practical point: that man was put on restricted diet and proper medicinal treatment, and in a week had improved decidedly. At the end of three months his vision was 4/5. His condition continued good until a year later when he died of some cerebral vascular lesion. Dr. Jackson said that he had seen several cases in which good vision was restored by paying attention to the temporary failure of circulation.

DR. A. R. BAKER, Cleveland, spoke of the importance to the ophthalmologist of the sphygmomanometer. Dr. Baker said that for a great many years he was able to recognize the condition of the fundus in which he had a suspicion of high blood tension. Of course, when there were hemorrhages he could speak positively, but when he could simply say that there was a little tortuosity of the vessels and would urge on the patient the importance of changing his method of living, his advice was usually unheeded. Such patients often congratulated themselves on being particularly well; one, a doctor, slapped himself, and said, "There is not a healthier doctor in Cleveland." He died within the year. When this apparatus was applied to the patient's arm, and the patient was shown his definite high tension and it was explained to him that the life insurance companies would not take him as a risk, Dr. Baker said this offered a definite fact to emphasize the therapeutic measures. Dr. Baker used to try to refer these patients back to the general practitioner, but found that most of them had not such apparatus and didn't know how to use it when loaned to them. Dr. Baker said that the instrument should be used every day, and that it was not necessary to refer patients to the general practitioner for its application

Dr G F. Keiper, Lafayette, Ind , said that he had found a great deal of angiosclerosis in the young as well as the old and had come to believe that the instrument for measuring blood pressure was just as essential as the ophthalmoscope Dr Keiper thought the contention of Janeway correct, namely, that instead of the narrow cuff the broad cuff should be used, and that observations should be based on the use of the broad cuff with the mercury manometer. He added that the kind of instrument used should be recorded because there was bound to be variation of any reading of the Riva Rocci instrument in comparison with the others

Dr Melville Black wished to emphasize the importance of determining the blood pressure by actual tests. He said that it was impossible to determine it by the appearance of the retinal circulation High blood pressure or low blood pressure might cause the same appearance in the retina and one should not be positive in the belief that it was always high blood pressure, it might be as Dr. Jackson had said, low for that individual.

HEMORRHAGE INTO THE VENTRICLES.

ITS RELATION TO CONVULSIONS AND RIGIDITY IN APOPLECTIFORM HEMIPLEGIA.[*]

ALFRED REGINALD ALLEN, M D
Instructor in Neurology and in Neuropathology in the University of Pennsylvania.
PHILADELPHIA.

The question to what extent the upper motor neurons are initiative in their function must of necessity be speculative. But since the advent of the theory of definite cerebral localization for well-ascertained function, since the increase of our knowledge of the association tracts and their importance psychologically, the concept of the upper motor neuron as a free agent in initiating its own stimulus becomes more and more untenable. To-day it would seem that the normal motor impulses from the Rolandic region are set in motion from impulses from other parts of the brain transmitted through association tracts.

Now muscular movement—for example, of the right side of the body, face, arm, trunk and leg—may be volitional, in which case it can be considered reflex to psychic stimulation. It may be due to the local action of some circulating poison, either stimulating the perikaryon or its neurons directly, or rendering them so hypersensitive to afferent impulses that, whereas normally there would be no reflex action, in the hyperexcitable condition there is a discharge of motor impulse; this is probably the case in uremia. Intracranial pressure, unless very gradual, is able by direct irritation to cause a motor discharge; and intracranial pressure as well as irritative lesions acting on the right cerebellar lobe can cause stimulation of the motor neurons of the left motor cortex, as in Weber's cases.[1] Electricity applied to the motor cortex or the internal capsule is also capable of causing motor functional activity. Lastly, and from the standpoint of this work of most importance, stimulation or irritation of the high sensory system, either of their perikaryons in the optic thalamus or other basal ganglia, or of their axons in the white matter of the centrum, is in all probability capable of causing motor impulses—the pure cerebral reflex.

The subject of convulsions and rigidity in apoplectiform hemiplegia is mentioned in a casual unsatisfactory way by Déjerine,[2] Strumpell, Brissaud[4] and Leube,[5] all of whom state that these symptoms point to the rupture of the hemorrhage into the ventricles. Nowhere have I been able to find any attempt at a physiologic explanation on this hypothesis.

Before considering my cases it is necessary to deal with the question of the possibility of stimulating the axons of the upper motor neurons when they are separated from their perikaryons. Weber[1] denies this possibility in no uncertain language:[6]

> That a direct stimulation of the pyramidal fiber can cause convulsions or rigidity is against all experimental and clinical experiences

Against this *ex cathedra* dictum of Weber's I would call attention to the work of Beevor and Horsley,[7] who succeeded in mapping out the internal capsule of the Bonnet monkey and the orang-outang by means of the secondary faradic current.

Hoche, in three articles,[8] discusses experimental work that he did on the cut end of the spinal cord in criminals who had just been beheaded. He used the faradic current, and although much of his work was negative and seemingly corroborative of Weber's statement, yet in the case where he made his test with least delay after decapitation his result speaks as positively in the affirmative as Weber's in the negative. Hoch's first article[9] says:

> According to the previous accounts I had expected little action; therefore, so much the more surprising was the effect. The corpse, which was lying flat, raised both its arms, bent at the elbow-joint, and with clenched fists, up in the air, the thorax raised itself in inspiration (so that with repeated stimulation the stump of the neck began again to bleed, due to the pump-like action of the thorax) and both legs were in tonic extension.

Hitzig[10] called attention to the fact that the excitability of the central nervous system rapidly failed after exsanguination. This accounts, it seems to me, for many of Hoche's negative results. I have found the lateral columns of the spinal cord in exsanguinated dogs incapable of stimulation. Morat[11] says:

Vulpian has devised an experiment on this disputed point which is decisive. In a rabbit or dog, after it has been put under the influence of ether, he lays bare the spinal cord for a length of six to ten centimeters above its lumbar enlargement: he cuts all the roots which correspond to this length (in order that he may not have to take into account the movements which would result from this stimulation by the diffusion of stimulating current). *He cuts the cord in* the most anterior portion of the region which has been laid bare and, throughout the extent of the latter, removes the posterior columns, a portion of the lateral columns, and as much as possible of the gray matter, in such a way that the anterior or anterolateral columns (according to circumstances) thus separated are only connected with the cord by their posterior extremity. If the anterior extremity of the columns isolated in this way be pricked or compressed, somersaults are provoked: that is to say, contractions of the muscles of the hind quarters of the animal and movements of the tail. If, by following the anterior fissure, the two anterior columns be separated with exactitude, the one from the other, by a longitudinal incision, it is observed, by stimulating one of them, that movements much stronger ensue in the corresponding limb than those arising in the limb of the opposite side.

Vulpian[12] gives a very similar experiment in his *"Lecons sur la physiologie générale et comparée du système nerveux,"* but I have not been able to find the original of Morat's quotation.

I have been unable to cause convulsive movements by stimulating electrically the lining of the lateral ventricles of the dog.

The pathologic material of the following cases has been generously given to me by Dr. Spiller, to whose kindness I am very deeply in debt.

CASE 1.—*Patient.*—H. J., female, aged 44, while doing her housework on the morning of Jan. 4, 1905, became faint and sat down on a chair, shortly afterward, falling to the floor unconscious.

Examination.—At the Philadelphia Hospital on the same day a right hemiplegia was demonstrated. The right upper limb was flexed at the elbow joint and efforts to straighten it met with much resistance. Both limbs on the right side could be moved but much less freely than the limbs of the left side. The patient's speech was thick and unintelligible and her answers were made in monosyllables. Her mouth was drawn to the left. In testing the reflexes it was doubtful whether any patellar tendon jerk was present on either side. Ankle clonus could not be elicited. The Babinski reflex was present. Although the patient had a tendency to stupor when brought to the hospital, yet she could be aroused and answered questions sensibly.

Clinical History.—At 11 a. m., January 15, the patient began to have convulsive attacks with unconsciousness. The convulsions began in the right side of the face, then extended to the right arm, and after that to the right leg, the head being turned to the left and the eyes to the right. These convulsive seizures lasted from three to five minutes. Later the convulsions became alternate, first on one side and then on the other. The side which was not involved remained absolutely flaccid. Rarely the convulsion involved both sides at once. The tongue was bitten frequently. The levator palpebrarum muscles, the occipitofrontalis and all the facial muscles were implicated in these convulsive seizures. At times the mouth was drawn strongly to the left but never to the right.

At 5 p. m. of this day a lumbar puncture was performed and about 15 c.c. of a reddish cloudy fluid were withdrawn. This at first dropped quite rapidly but was not apparently under much pressure. By this time the convulsions had become milder, but were still alternating on each side. The patient died January 15, the day of the onset of the convulsions.

Autopsy.—On horizontal section a large hemorrhage of recent development was found in the left lenticular nucleus It extended into the internal capsule and had broken into the lateral ventricle at its anterior end. The hemorrhage was found in both lateral ventricles but chiefly the left. The extent of the lesion posteriorly was such that it involved the entire posterior limb of the internal capsule and the posterolateral part of the optic thalamus.

The clinical history of this case would indicate that the hemorrhage was of very gradual development. The convulsions on the left side were probably due to irritation of the right motor cortex from increased intracranial pressure.

CASE 2.—*Patient.*—C. S., male, aged 50, laborer, white, was brought into the Philadelphia Hospital unconscious and without data as to past history. Soon after admission (Oct. 2, 1906) he began *having general convulsions involving all* limbs, but the left side somewhat more than the right.

Examination.—When tested between convulsive seizures the right arm would drop flaccidly when raised, but the left arm would be replaced by the patient. The notes recorded under date of October 4 state that there was present conjugate deviation of head and eyes to the right. When the right arm and leg were pricked with a pin there was no movement on the right or left side. On pricking either limb on the left side, the limb so irritated was drawn up. The patellar tendon jerks on the right side were marked + and on the left side ++. There was no ankle clonus on the right side and a quickly disappearing ankle clonus on the left. The Babinski reflex was present on both sides. The left leg tended to develop a general clonus when the tendon reflexes were examined. There were involuntary evacuations of the bladder and rectum. By testing the patient with his feeding-cup a right lateral homonymous hemianopsia seemed to be present The left pupil was larger than the right and both reacted to light.

Autopsy.—An horizontal section made through the left cerebral hemisphere, at a level just above the tenia semicircularis, showed an extensive hemorrhage entirely destroying the left lenticular nucleus at this region and breaking into the left lateral ventricle anteriorly and posteriorly and encroaching mesially on the optic thalamus. A section one centimeter below this showed the site of the hemorrhage *moved outward, the head of the caudate nucleus at this level* being uninvolved, the lateral part of the putamen being the farthest encroachment medianward on the lenticular nucleus. There was at this level a slight involvement of the posterior part of the posterior limb of the internal capsule.

CASE 3.—*History.*—J. E., male, aged 28 years, white, five weeks *prior to his admission to the Philadelphia Hospital,* Sept. 16, 1906, took a dose of quinin, he thought about fifteen grains, for "chills and fever" from which he had been suffering about one week. A "couple of hours" after this dose he felt very sleepy, lay down, became unconscious and remained so for three days. When he regained his consciousness again he was paralyzed on the left side, his speech was thick and he could not see clearly. He regained a fair amount of power in this paralyzed side. Although he had complete incontinence of bladder and rectum for one week after the attack yet it is recorded that his condition had so far improved in this respect that if he attended to himself at once when he felt the inclination he could control his sphincters. On Nov. 16, 1906, he began to have repeated convulsions. These *followed one another with irregular intermissions until* he died the same day. There is no description of the convulsions on his record.

Autopsy.—The brain bulged considerably in the right frontal and right frontoparietal regions with flattening of convolutions and obliteration of sulci. On horizontal section there was found a large hemorrhage which had in all probability started in the lenticular nucleus on the right and had torn its way *both anteriorly and posteriorly into the lateral* ventricle. The entire ventricular system, right and left, was filled with blood. The aqueduct of Sylvius and the fourth ventricle were distended and filled with blood. The anterior part of the callosomarginal region on the right had become greatly distended and had encroached on the left hemisphere. The destruction of tissue in the *right cerebrum* was very great and involved the anterolateral part of the optic thalamus. There was also some destruction of tissue in the left cerebrum, chiefly about the anterior extremity of the lateral ventricle.

---

[12] Vulpian, A.: Leçons sur la physiologie générale et comparee du système nerveux, Paris, 1866, p. 360.

CASE 4.—*History.*—W. L., male, aged 52, had an apoplectic attack in November, 1903, with unconsciousness, after which he was hemiplegic on the left side. He was taken to the Hospital of the University of Pennsylvania. The unconsciousness lasted twenty-four hours, during which time there was a convulsive seizure. In June, 1904, he had another attack of unconsciousness with convulsions and after this, three similar attacks about six weeks apart. He became able to walk afterward but had only a little control over his left hand. On Aug. 8, 1905, he had about fifteen convulsions in which the right arm was in clonic spasms, preceded by a conjugate deviation of the head and eyes to the right. The convulsive condition then affected the left arm and the lower limbs. The whole body was then the subject of clonic spasms followed by a brief period of tonic contraction. Apparently the facial muscles were equally involved. On Nov. 20, 1905, the patient slipped and struck the right side of his forehead against a door. He was put to bed in a perfectly conscious state, but gradually lost consciousness. In about half an hour after he was unconscious he began having convulsions starting in the left arm and extending to the left leg, left side of the face and finally over the entire body. He had a number of these convulsions following one another in rapid succession and lasting from one-half to two minutes. At times there existed almost a tonic condition. These convulsions commenced about 1:30 p. m. and the patient died at 5 p. m. The convulsions stopped some time before death and Cheyne Stokes respiration set in.

Autopsy.—The hemorrhage probably started in the putamen of the right lenticular nucleus. Mesially it had encroached on and involved the internal capsule and optic thalamus. Posteriorly it had torn through the posterior part of the posterior limb of the internal capsule into the lateral ventricle. Externally it had torn through and completely obliterated the external capsule and was in close juxtaposition to the cortex of the island of Reil. Anteriorly it had torn through the white matter which forms the outer wall of the extreme end of the anterior horn of the lateral ventricle and had likewise passed externally, via the white matter, past the anterior extremity of the insula, to within one centimeter of the cortex of the foot of the third frontal convolution. All the ventricles were filled with blood.

CASE 5.—*Patient.*—C. H., male, aged 80, born in Germany, was brought to the Philadelphia Hospital unconscious on March 6, 1906.

Examination.—The right arm and leg were paralyzed, the face was slightly drawn to the left and the right nasolabial fold was almost obliterated. The right eye was not completely closed and offered no resistance when an attempt was made to open it. There was conjugate deviation of head and eyes to the left. The tongue in the mouth deviated to the left, protrusion, of course, being impossible. The right upper limb was flaccid but the right lower limb was spastic.

Clinical History.—At first there was right hemianesthesia but this was of only short duration, as Dr. Spiller made a note on March 7 to the effect that a pin prick was perceived in the right side of the face and in the right upper and lower limbs. By March 8, the right upper limb had become spastic. Slight involuntary jerkings in the right lower limb were also noted. The stupor was too great to make any test for hemianopsia. On March 10 the right hemianesthesia was again noted. The patient died March 11, 1906.

Autopsy.—The hemorrhage, which was in the left cerebral hemisphere was studied in three horizontal planes about one centimeter apart. The highest section was at the level of the top of the lenticular nucleus, and the hemorrhage here involved the external and posterior part of the thalamus and the white matter external to it. There was only a thin layer of white matter between the hemorrhage and the cortex of the highest part of the insula. The section one centimeter below this showed that the hemorrhage had involved the posterior half of the lenticular nucleus and had also cut the posterior two-thirds of the posterior limb of the internal capsule. In the lowest section, one centimeter below the preceding, there still remained a small hemorrhagic area involving the posterior edge of the inner portion of the putamen and also the posterior edge of the globus pallidus and destroying the posterior extremity of the posterior limb of the internal capsule and here breaking into the lateral ventricle.

CASE 6.—*Patient.*—N. B., male, aged 60, white, was admitted to the Philadelphia General Hospital, April 4, 1903. The diagnosis of his condition on admission was pseudobulbar palsy and his previous history and examination are so foreign to the subject at hand that I shall omit them, passing at once to the record of relevant facts.

Clinical History.—On Sept. 4, 1904, the patient complained of feeling bad and was apprehensive that something was going to happen to him. On September 5, the orderly noticed that the patient was trembling much more than usual when being put to bed. At 6:30 p. m. of that evening the patient had a convulsion lasting about three minutes. There were several convulsive seizures following this first and lasting about the same time, but they are not described, so the question of consciousness, location and character can not be determined. At 7:15 p. m. the patient had an attack lasting about one hour, in which the entire right side of the body was in a state of clonic convulsion, the left side remaining free from movement. During this convulsion he was unconscious, bit his tongue and frothed at the mouth. After this seizure he remained quiescent until 1 a. m., Sept. 6, from which time to 7 a. m. of the same day he had twelve convulsions.

He had, in addition to unconsciousness, conjugate deviation of his head and eyes to the left. A pin prick on either side of the face caused movement of the face, but if the limbs were pricked there was no response. Dr. Spiller's notes record that when the right upper limb was raised and allowed to fall it did so as though dead. Both upper limbs were spastic, though the right was more so than the left. The biceps tendon jerk was exaggerated in both sides. When the left upper limb was stuck with a pin there was voluntary movement, but the right, under the same conditions, exhibited no motion. Both the lower limbs were spastic, both had exaggerated patellar tendon jerks and Babinski reflex. There was persistent ankle clonus on the right but not on the left side.

Autopsy.—Examination of the brain revealed a small cortical and subcortical hemorrhage just posterior and inferior to the angular gyrus. This lesion passed inward to within a few millimeters of the lateral ventricle. The optic thalamus was uninvolved.

CASE 7.—*Patient.*—J. W., male, aged 37, white, was admitted to the Philadelphia Hospital on May 10, 1905, suffering from tabes dorsalis. His previous history and physical examination as to his tabetic trouble I shall omit.

Clinical History.—He was allowed to go out on July 4, and next day, July 5, he was brought back by the police. He had been drinking and developed that evening a right-sided hemiplegia without aphasia or loss of consciousness. Until December there was nothing of moment to record except that his hemiplegic condition was much improved. On the evening of December 12 he fell unconscious. His head and eyes were rotated toward the right. On December 14, it is recorded that the face was drawn toward the right and that the left nasolabial fold was obliterated. A weakness in closing the left eye was also noted. The tongue had a fine tremor and deviated to the right. The power in the upper extremities was diminished. The grip was much weaker in the left hand than in the right. The left upper extremity was spastic and there was complete loss of power in the left lower limb with flaccidity. He was able to move the right lower extremity freely. The Babinski reflex was present on the left side. All the other reflexes of the lower limbs were absent presumably on account of the tabetic lesion. The patient gradually lost ground and without exhibiting any additional symptoms worthy of note died on December 26.

Autopsy.—A horizontal section through the cerebral hemispheres just below the highest part of the fornix showed a hemorrhage involving the fibers which in a section lower down, if the optic thalamus and lenticular nucleus were cut, would form the posterior part of the posterior limb of the internal capsule. This hemorrhage had broken through into the lateral ventricle posteriorly. The center of this hemorrhage was evidently well above this level, possibly posterior and mesial to the roof of the body of the lateral ventricle. The posterior part of the corpus callosum was involved in this hemorrhage.

In a section one centimeter below this, there was found in the posterior part of the putamen of the left lenticular nucleus an old cyst which evidently caused the right hemiplegia. On the right side there was found a cyst the size of a kidney-bean involving the anterior part of the putamen of the right lenticular nucleus and encroaching on the external capsule.

Case 8.—*Patient.*—G. R., male, aged 77, white, born in Germany, was admitted to the Philadelphia Hospital on July 19, 1904, with the history that he had had the night before a sudden attack of unconsciousness with a left hemiplegia. There was slight deviation of the eyes to the right, the left side of the face was smoother than the right and the tongue deviated toward the left. The reflexes were all lost on the left and the Babinski reflex was present on the left and absent on the right. He could not perceive when stuck with a pin in his left upper or lower limb. He died on July 25, 1904.

Autopsy.—A horizontal section through the right cerebral hemisphere just below the corpus callosum showed a hemorrhage destroying the posterior part of the lenticular nucleus and most of the posterior limb of the internal capsule, especially its posterior part. A section one centimeter below this showed the hemorrhage extending for about one centimeter into the temporal operculum. The optic thalamus was uninvolved.

Case 9.—*History.*—I quote from two letters written to Dr. Spiller by Dr. Thomas R. Neilson, in regard to the patient, Miss H., aged 50: "I was called to see her between 9 and 10 o'clock on the evening of April 19, 1904, and found her in bed, completely unconscious. And from her brother and his wife I got the information that she had fallen down in her room some time earlier that evening. When I saw her, her condition, as well as I now remember it, was as follows: Complete unconsciousness, complete paralysis of all the extremities; no response to pricking fingers or toes with a pin; pupils did not respond to light and were moderately contracted, respiration puffing but not accelerated; pulse 84 with no marked degree of tension. The mouth was, I think, slightly drawn to the left, but I will not be positive of this. In a short time, say twenty to thirty minutes, I recollect that pricking the fingers of the left hand excited muscular contraction of that arm resulting in flexion of the elbow. I saw Miss H. a second time on April 21, at about noon; she was then unmistakably dying. Paralysis was complete, temperature elevated, pulse weak and frequent, respirations labored and stertorous. She did die that day." There was no history of convulsions in this case.

Autopsy.—I quote from Dr. Spiller's postmortem record: "A large hemorrhage was found filling the whole of the left lateral ventricle and not extending into the right ventricle; the substance of the brain was implicated in the lesion only near the anterior part of the left lateral ventricle. The attack had lasted forty-eight hours, and convulsions are said to have been absent."

Case 10.—*Patient.*—W. U., male, aged 72, white, born in England, presented a history which does not bear on the question at hand except that he had been an excessive user of alcohol and had had sugar in his urine for the past fifteen years.

Previous Attack.—The patient retired at his usual time on the night of March 14, 1905, and was found next day at noon lying at the side of his bed in a semi-conscious condition with a left hemiplegia. In this condition he was sent to the Hospital of the University of Pennsylvania.

Examination.—Dr. Spiller's notes record that there was a semi-stupor and that the left side of the face was flattened, the nasolabial fold on that side having disappeared. The eyelids on the left could not be closed as firmly as on the right. The forehead wrinkled better on the right than on the left side. The tongue deviated to the left when protruded. The masseter contracted equally well on both sides. The left upper limb fell lifeless. The patient made no movement with his left lower limb. He seemed to present a left homonymous lateral hemianopsia for when his feeding-cup was brought to him from his left side he made no attempt to take it. Sensation to pin-prick on left side was preserved. The biceps and triceps tendon jerks were not very prompt on either side. The patellar and Achilles tendon jerks were lost on both sides. The Babinski reflex was present on the left but not on the right.

Without any marked change except deepening stupor and Cheyne-Stokes breathing the patient died on March 26, twelve days after his attack. There is no record of convulsion.

Autopsy.—On horizontal section there was found a hemorrhage bounded anteriorly by a line passing through the genu of the internal capsule. Posteriorly the hemorrhage had broken through the posterior part of the optic thalamus into the lateral ventricle. The posterior limb of the internal capsule was destroyed.

SUMMARY.

Four patients (Nos. 1, 2, 3, 4) had convulsions, rupture of the hemorrhage into the ventricles and involvement of the optic thalamus.

One patient (No. 5) had rigidity, rupture of the hemorrhage into the ventricles and involvement of the optic thalamus.

One patient (No. 6) had convulsions, no hemorrhagic rupture into the ventricles but an involvement of the cortex and subcortical white matter of a sensory region.

Three patients (Nos. 7, 8, 9) had no convulsions and no optic thalamus involvement. Two of these (Nos. 7 and 9) had ventricular inundation; one of them had not.

One patient (No. 10) had no convulsion and had optic thalamus involvement. (It is but just to say that this last case was not sufficiently under observation so that it could be said with certainty that there was no convulsive action.)

My conclusions are:

1. Ventricular inundation in cerebral hemorrhage has no etiologic bearing on the convulsions or rigidity.

2. Purely tentatively and basing my opinion on the findings in these ten cases, I conclude that convulsions and rigidity in apoplectiform hemiplegia are frequently due to an involvement of the optic thalamus, or the corticothalamic sensory fibers, with the necessary proviso that enough of the posterior limb of the internal capsule remain uninjured to convey the motor impulses.

3. Convulsions and rigidity in apoplectiform hemiplegia may be caused by a sudden or rapid increase in intracranial pressure due to cerebral hemorrhage, even though the optic thalamus and the corticothalamic sensory fibers are uninvolved. In this case, as above, there must be a sufficient preservation of the motor part of the internal capsule for the transmission of impulses to the parts concerned.

4. It is altogether unlikely that pressure or chemical change acting on the motor axons of the centrum or internal capsule—these axons having been severed from their perikaryons by the hemorrhagic process—could exert a stimulating action sufficient to cause convulsions or rigidity.

DISCUSSION.

Dr. William G. Spiller, Philadelphia: It has been a question in my mind for many years whether or *not* convulsions are caused by hemorrhage into the ventricle and may be considered as indicative of this lesion. I *am glad*, therefore, that Dr. Allen has studied this subject so *carefully*. I do not believe that a hemorrhage into the ventricles always produces convulsions and I doubt whether convulsions occurring with the onset of hemiplegia may be regarded as indicative of ventricular hemorrhage. I am glad that Dr. Allen has brought out another point clearly, viz., that when the motor tract is completely cut across by hemorrhage, it is not probable that convulsions will occur. A case of this kind was presented by Dr Boehrock. A man had hemiplegia from cerebral hemorrhage, and convulsions occurred on the side on which the hemorrhage was, but not on the other. My explanation was that the motor fibers were cut on the side of the hemorrhage, and therefore convulsions occurred on the same side, but not on the opposite side, from general irritation of the brain.

DR. A. R. ALLEN, Philadelphia: In answer to Dr. Spiller's question as to the preservation of the motor tract in the cases that had convulsion: One case suffered considerable damage to the entire posterior limb of the internal capsule, which damage I think was late in the hemiplegic attack. I take it for granted that at the time the patient had the convulsions and rigidity, the hemorrhage had not been as extensive as it was found at the autopsy, that being indicated by the clinical history.

ZONULAR OPACITY OF THE CORNEA.*

F. C. HEATH, M.D.
Professor Clinical Ophthalmology, Indiana Medical College; Secretary Indiana State Medical Association.
INDIANAPOLIS.

Zonular opacity of the cornea is described very briefly in the majority of text-books. Some do not mention it at all, a number dismiss it with a short paragraph, while a very few give it a page.

Nettleship contributed an article of about 25 pages on this subject to the *Archives of Ophthalmology*, in 1879, giving in detail 22 cases seen by various observers. Bock, Graefe, Usher, Best, Leber, and a few others have also investigated the subject quite extensively. The first description was given by Dixon in 1848, followed by Bowman, who went more deeply into the matter. Dixon called it calcareous film of the cornea, finding calcium carbonate and phosphate in the parts removed. Graefe named it band opacity, while Fuchs employs the term given at the heading of this paper. It has been more frequently designated as ribbon-like opacity, or keratitis, and calcareous keratitis.

Zonular opacity occurs in two forms, primary and secondary; the former in eyes otherwise normal, the latter in those blind from glaucoma, iridocyclitis or other intraocular affections. While neither form is common, the primary is much rarer than the secondary form.

It has been described as having the appearance of minute dots crowded together, "punctiform opacities," a gray stripe stretching across the cornea, most marked a little below the center, on the part exposed when the eye is open. The opacity usually begins about the same time at two points near the inner and outer corneal margins, meeting later in the middle line. Some cases have begun centrally. There is always a narrow, transparent zone about the margin.

The progress of the disease is extremely slow, usually continuing for years, although Wells saw one case develop in a few months. Sooner or later both eyes are almost certainly involved, but one may be affected quite a number of years before the other. In some cases there are spells of severe pain, while in others (probably the majority) there is no pain at all. There is no indication of ulceration, the corneal epithelium being smooth and unbroken, in the primary form.

This disease occurs principally in men and after middle age. In 14 cases tabulated by Nettleship, all but 4 patients were over 45 and only one patient was under 30.

The pathology of this affection consists in the deposit of hyaline masses and lime in the upper layers of the cornea, or, as it has been otherwise expressed, "hyaline degeneration of corneal cells that later become calcareous." Bowman's membrane may be the part first affected, and there may be also proliferation of connective tissue.

The etiology is obscure. The location of the trouble in the exposed portions of the cornea has led to belief in a local cause. But if this were true, why is it found in so few persons? Must there not be some predisposing tendency? In gouty subjects, or those with uric-acid diathesis, the nutrient fluid of the cornea, according to Leber, is supposed to be richer in lime salts and these may become deposited by evaporation. Swanzy says that in primary cases the cause of the degeneration is simply loss of vital energy in the cornea from vascular changes, attributed by Nettleship to gout, renal disorders and cardiac affections. Fuchs saw a case in a physician who had blown calomel into his eyes for years, and Toplanski met the disease in hatmakers whose eyes were irritated by flying pieces of hair. Graefe believed that, as the secondary form of this disease followed glaucoma, so the primary form was akin to the glaucomatous process or would eventually go over into glaucoma. As would be expected, these cases are made worse by atropin.

Sight has been restored or improved in some cases by scraping the cornea, the lime deposits coming away in flakes. In other cases iridectomy has proved of great advantage. May advises the use of carbonate of soda after scraping. Sellerbeck advocated the hourly use of 5 per cent. hydrochloric acid, while Nettleship tried nitric acid in one case without effect. Noyes stated that these cases rarely are benefited by any method, and Fox, in his text-book, in 1904, says treatment is of no avail. Guillery, of Cologne, has recently tried ammonium chlorid, beginning with a 2 per cent. solution and gradually increasing to 20 per cent. While his article[1] is headed "Calcareous Opacity of the Cornea," it is evident that he means opacity from lime burns, a very different thing from the subject of this paper.

The following case from my records, the only case of primary zonular or calcareous opacity of the cornea seen in 17 years of eye-work, will serve to illustrate the points of this disease. It is also worth recording on account of its rarity and the gratifying result of operative treatment. Indeed, all cases of such a rare disease, about which there is so little definite knowledge, should be reported fully.

Mr. W. W., born in England; first seen by me Feb. 23, 1897, when he was 34 years old. There was, then, a slight haziness of left cornea to the outer side, and he suffered considerable pain. He was a bricklayer and engaged at this time in the construction of sewers. On the theory that the keratitis might be malarial, he was given quinin, followed by arsenic. (De Schweinitz[2] described a peripheral annular parenchymatous infiltration of the cornea, of malarial origin, separated from the margin by a zone of clear tissue.) Our diagnosis seemed to be confirmed by the fact that the pain soon yielded to the antimalarial treatment. He was seen only a few times in 1897 and 1898, and then passed from observation for a number of years. The opacity evidently increased very slowly in extent and density.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

1. Arch. Ophth., Sept., 1907.
2. Philadelphia Polyclinic, 1895.

September 1, 1904, he returned, complaining of pain in the right eye, the vision of which was normal, but there was a faint, almost imperceptible, haze near the outer margin and rather low down. The opacity of the left eye was now very dense and covered most of the cornea, being surrounded by a zone or rim of clear tissue, very narrow, and nearly the same width in all parts of the circumference, except the upper margin, where it was a little wider. Vision in this eye was reduced to light perception only.

The opacity in the right eye progressed very slowly. Attacks of severe pain occurred at irregular intervals without a particle of redness of the ball. Tension was at all times normal. The pupil was round and responsive to light. He was given quinin and arsenic again, without any apparent effect. Analysis of urine showed no albumin or sugar. He had the appearance of being plethoric, was rather fleshy, with red cheeks. He was not a user of alcohol in any form, but was a great meat eater.

His internal treatment for a long time consisted in the alternate use of salicylate of sodium and iodid of potassium. Pilocarpin and holocain locally, with the addition of dionin a little later, seemed to modify the pain, and after a few months the attacks occurred at longer intervals and then ceased altogether. The dionin had no effect on the opacity. The cessation of pain and the long preservation of good vision led us to believe in the efficacy of the treatment. But it is more than likely that it was simply the naturally slow progress usually seen in such cases. A very weak solution of atropin was tried at the suggestion of one of my colleagues, who, however, advised its discontinuance at the next visit, noting some loss of vision. This accords with Graefe's view that atropin is contraindicated in zonular opacity. (In Nettleship's article mention is made of the use of atropin in several cases with no statement as to its effect further than that the pupils dilated readily.)

My patient was sent to Dr. James M. Ball of St. Louis, with a note asking if this were not a case of zonular or ribbon-shaped opacity, pictured and described on page 335 of his textbook. He replied that it was a typical case, and suggested an iridectomy downward and inward on the left eye. I could not see the advantage of this, as the rim of clear tissue in that direction was so very narrow. It looked to me that an upward iridectomy would be more promising, if any were done, as the rim was wider here than at any other part. But the patient was averse to any operation just then, the vision being still good in the other eye.

The faint opacity seen first in the right eye gradually extended upward and toward the center of the cornea, another band starting a few months later from near the inner margin and extending also toward the center. For a number of months the space directly in front of the pupil was not encroached on. Finally, a very faint haze appeared there, reducing distant vision from 20/20 to 20/40, where it remained for some time, falling to 20/70 for a while and then returning to 20/40. For nearly two years vision was good enough for his regular work as foreman in one of the departments of the Malleable Castings Company. But finally the opacity over the pupillary region deepened and extended a little higher, so that work had to be given up. He could not see enough to go about by himself.

Early in October, 1906, assisted by my colleague, Dr. F. A. Morrison, I proceeded to scrape off a space directly in front of the right pupil, and two weeks later made another scraping, this time assisted by Dr. W. N. Sharp, who examined some of the scrapings under the microscope, finding degenerated cells, probably hyaline, but no lime crystals. This did not flake out, as some have described it. Probably the other eye, in which the disease was more advanced, would have shown this. I regret that we did not try the effect of acids.

The scraping was followed by the use of weak carbonate of soda solution, as suggested by May, but, although we had scraped as much as we dared, there was no improvement of vision. In fact, it was temporarily made worse.

After the inflammatory reaction had subsided, he was sent to the Indianapolis City Hospital, where I did an upward iridectomy, resulting in 15/40 vision with + 6. sph. = + 2. cyl., axis 180. This enabled him to return to work and earn as much as ever. This vision has been maintained now for more than a year.

About eight months ago he was helping a fellow workman, a sufferer from trachoma, drop medicine into his eye, and accidentally infected his own left eye, fortunately not the one I had operated on. Prompt treatment with strong solutions of silver nitrate at the office, and 1 to 4,000 bichlorid solution at home, controlled this well, and the good eye has never become infected.

It is interesting to note that there has been some improvement in the unoperated eye. At one time light perception alone existed, and in November, 1906, when the other eye was operated on, there was only faint shadowy perception of large objects, not enough to enable him to get about without being led, but the sight of this eye now is 10/200. Is this due to the internal use of salicylates and iodids? Has the local treatment for the trachoma or the irritation of that disease had any tendency to clear it up? Does the operation on one eye have any effect on the other? These questions are easy to ask, but very difficult to answer. I can give no satisfactory explanation. The opacity certainly looks less dense than formerly, especially directly in front of the pupil. In one of the cases given by Nettleship, Mr. Fairlie Clarke, under whose care the patient was, thought the central clear space in front of the pupil due to spontaneous chipping away of the film.

In view of the good result in this case, and in some of the cases reported by Bowman, Walton, Graefe, Nettleship and others, the statements of Noyes and Fox about the uselessness of treatment sound strange. Possibly they had in mind only the secondary form, occurring in eyes already blind, aside from the opacity, and therefore not amenable to treatment.

In conclusion, I would emphasize the interesting features of this case, the comparatively early age at which the affection began, the rather unusual pain in the first stages and the remedies therefor, the improvement in the vision of the unoperated eye, and the gratifying result of the iridectomy in the other. These circumstances, together with the rarity of this form of the disease and the paucity of the literature, seem to justify the detailed report of this interesting case.

427 Newton Claypool Building.

DISCUSSION.

Dr. E. V. L. Brown, Chicago: So far as I know, no cases of primary zonular opacity have come to anatomic study and therefore the etiology is not clear. The secondary cases are explained on the basis of the hyalin and calcareous degeneration of the anterior part of the cornea and Bowman's membrane; many of these cases have been studied. I have sections from four or five cases and have looked them over in connection with this discussion. The main point, it seems to me, is the clearing up of the left eye. There are two possibilities. First, the gradual clearing of the infiltrate about the areas of calcareous degeneration may have taken place from the absorption of the fatty degenerated infiltration, in the manner contended for by Wossius, who has recorded the findings of fatty substance in the anterior part of the cornea; yet there was no inflammation of this eye at any time. Gradual clearing might occur without any vascularization of the cornea, but any marked change would be accompanied by some so-called inflammatory phenomena. The other cause I have thought of is also accompanied by vascular changes attendant on the trachoma, which appeared in the eleventh year of the case. There is just a possibility that these calcareous infiltrations in the anterior part of the cornea were sequestrated and thrown off just as any foreign body would be, and that enough of this took place in the central area of the cornea to allow clearing. The case was followed up for some time after improvement of vision and there has been no decrease which would seem to make this an impossible explanation. When there has been such a defect, essentially an ulcer, and the epithelium grows over it again, there is invariably the development of connective tissue between the stroma and the depressed epithelium. The exhibition of fluorescein at this time would have determined if there was an ulcer and I would like to ask if it was used at any time for the determination of a defect in the epithelium. I only suggest this as a possible means of the clearing.

Dr. L. H. Taylor, Wilkes-Barre: I have seen only one case of this kind and that not in my own practice. In this there were two bands, one in each eye; one at an axis of 45 and the other of 135 degrees. It was perfectly symmetrical, all the way of the same width, and the tissue above and below perfectly clear.

Dr. Edward Jackson, Denver: I have seen three cases of primary opacity of this kind at comparatively long intervals. The first was seen very soon after I entered practice. I saw this patient for some years and there was no change in the opacity up to death. The second one I saw once or twice at the Wills Eye Hospital and the third I have seen within the last two years. The opacity in all three was characteristic, involving the part of the cornea exposed in the palpebral opening, but showing a transparent position between the margin of the opacity and the margin of the cornea. There was no history of previous disease and no evidence of any other disease.

The last patient had noticed failing vision for seven or eight years; she had not attempted to do any reading or sewing for five years. When she came to me the best obtainable vision was 4/45. She had lived in Kansas and had been much exposed to dust for many years. The film was gray, slightly brownish and consisted of minute dots. The cornea reflex was absolutely perfect and the epithelium perfectly smooth. In all these cases I advised scraping the cornea. The first two did not submit. This one did and under holocain the film was scraped away. The central densest portion scraped away easily; it came away in flakes. Where the opacity was less dense it did not flake that way, and was more difficult to remove. The operation was done under local anesthesia and without pain, but was followed by severe pain, such as we have from abrasion of the cornea, which lasted some eight or ten hours, and gradually passed away. It was relieved a good deal by instillations of holocain. At the end of a week vision had fallen from 4/45 to 4/100. At the end of the second week, however, it began to improve, and at the end of three months the vision in one eye was 4/9 and in the other 4/12. The opacity appeared to be chiefly on the under surface of Bowman's membrane and consisted of isolated dots. I could not get any certain evidence that there was any calcium carbonate in the flakes.

Dr. F. C. Heath in answer to questions: Fluorescein was not used because the corneal epithelium was smooth, and I saw no indication for its use. There was no pannus following the trachoma. The film was grayish in color. I observed the same regularity of which Dr. Taylor speaks and the film was transverse.

Treatment of Hydrophobia in Ancient Times.—The *Tribune Médicale*, May 30, describes the old practice of immersing persons in the sea as a preventive and cure of hydrophobia, citing the legend that Euripides was saved by this means after having been bitten by a rabid dog. A number of cases are quoted from the historical records of the eighteenth century in which persons sought the sea as a preventive after having been bitten. One old chronicle comments on the death of an English lord from hydrophobia notwithstanding that he had been duly immersed in the sea: "This proves that there is no remedy for the imagination, and that people are cured less by the sea than by their imagination that they are cured." We learn from the case of a page of M. de Nevers, in the days of Henri IV., that when the thalassotherapy failed it was the practice to put a bullet through the head of the victim when the hydrophobia had declared itself. The page in question "died in peace just as they were on the point of firing a harquebus at his head."

Clinical Note

A TYPICAL CREST-SHAPED SEPTAL DEFLECTION,

WITH PRESENTATION OF SOME NASAL INSTRUMENTS.*

O. T. FREER, M.D.
CHICAGO.

In a deflected septum removed from a cadaver, the deflection was of the variety I have classified as crest-shaped (Fig. 1), because the apex of its angle of convexity consisted of a sharp, cartilaginous ridge ascending upward and backward parallel to the anterior border of the vomer, but lying about three-eighths of an inch below it. This variety of deflection I regard as the fundamental deformity in nearly all nontraumatic deviations, the anatomic condition consisting of a curving over of the incisor and superior maxillary crests and the anterior portion of the vomer into the naris of the convexity, associated with an overriding of these bony parts by an extension of the septal cartilage downward and backward, the lower limit of this cartilaginous extension forming the sharp crest referred to. It is this crest with a strip of the underlying bone which is so often sawed off, with but partial freeing of the patient's naris, while the more important obstruction due to the body of the deflection, of which the crest merely forms the sharp angle, is ignored. The cartilaginous strip mentioned is always found roughened on its inner surface where it is attached to the side of the bony septum, is present in most deviations of the nasal septum and has to be lifted off from the underlying bone before the latter can be found and resected. I regard the deviation in the bony septum as the main feature in the majority of non-

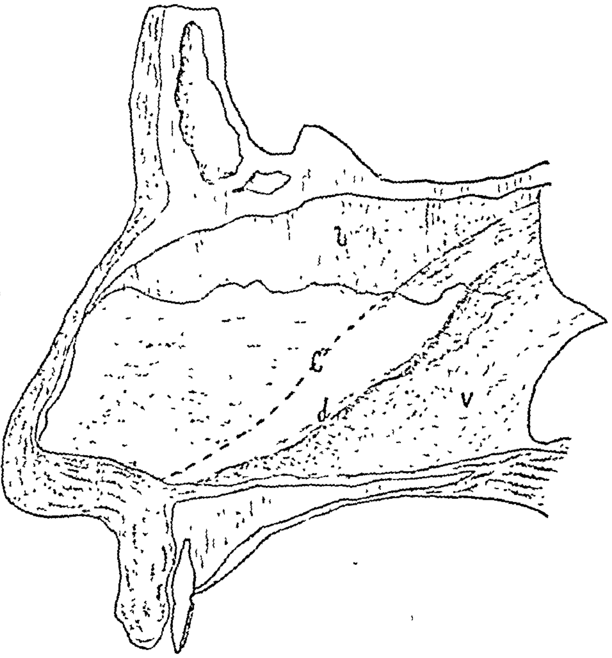

Fig. 1.—Lateral view of the nasal septum showing typical crest-shaped deflection with sharp cartilaginous crest, d; l, perpendicular plate of the ethmoid bone; v, vomer presenting convex surface of bony deflection towards observer; c, cartilage of the septum overriding the vomer downwards and backwards. The dotted line indicates the position of the anterior border of the vomer covered by the overlying cartilage. Drawn from specimen.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

traumatic deflections, a bend in the cartilage being merely secondary to it and only made the most of in most operative procedures for the correction of deviations because its position in the front of the nostril makes it a striking condition, while the bony deviation, lying deeper in the naris, is often overlooked or else ignored because the operator thinks that he has done enough in resecting the cartilage or because he hesitates to enter into the difficult removal of the bone in the depths of the nostril. Nevertheless, the bony deflection is often the worst obstacle to breathing and if left will have to be taken away at a subsequent operation.

The retractors shown (Fig. 2) are for holding the naris open during the submucous resection as I perform it, the improvement consisting of the substitution of a smooth, rounded lip for the thinner, sharper edge of the old style retractor which made it occasionally perforate the posterior flap on the side of the convexity of the deviation. In my method of operation three retractors are used for holding the nose open and I regard any form of nasal speculum as unsuitable for it.

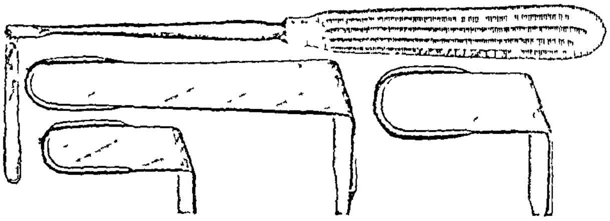

Fig. 2.—Freer's improved retractors for use in the submucous resection of the nasal septum.

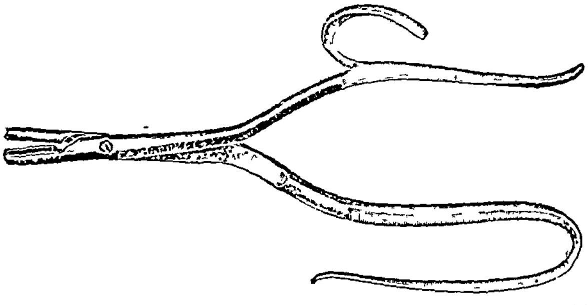

Fig. 3.—Freer's pernasal forceps for the removal of adenoid vegetations through the nose.

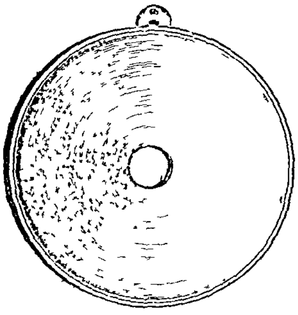

Fig. 4.—Short focus head mirror.

The pernasal forceps (Fig. 3) for the removal of adenoid growths through the nose I use exclusively for the operation. I do not employ the curette at all and postnasal forceps only where a marked deviation of the septum makes it impossible to use the direct nasal route.

There are three sizes of the forceps, the slenderer one being used on infants. The elasticity of the septum in children, their comparatively broad nasal channels and the rudimentary condition of their turbinated bodies makes the passage of the forceps easy. I do not expect these forceps to supplant the curette in popularity, but recommend them to those who wish to be sure that all adenoid masses are removed from places inaccessible to the ring knife, such as the choanæ, the posterior wall of the pharynx, or the fossa of Rosenmüller.

The short focus head mirror (Fig. 4) also shown permits a nearer approach of the eye to the ear and nose than is possible with the common longer focus laryngeal reflector found in the shops, as it has a focal length of but 8 inches. Common reflectors focus about 14 inches.

DISCUSSION.

Dr. J. F. Barnhill, Indianapolis: It has for a long time been my opinion that the curette, if properly constructed, is the ideal adenoid instrument, for with it the operator is enabled to remove, in nearly every instance, the entire mass of adenoid at one sweep. Since there is only one individual mass in any one person's throat, the term *adenoids* should be dropped for the reason that it gives the impression that there is more than one growth to remove and that, therefore, the curette or other instrument must be introduced more than once in order to be thorough. There is never but one adenoid and hence if the operator selects a curette as wide as will snugly fit into the nasopharyngeal space, and then follows out a proper technic as to the direction of making the sweep, one such sweep will cut away the entire growth and there should be absolutely no necessity of making a second or third sweep with the instrument. I will admit that rarely some portion of the growth remains in the choanæ. When such is the case an instrument such as Dr. Freer has shown would undoubtedly be serviceable in removing it.

Dr. E. Fletcher Ingals, Chicago: Dr. Freer spoke of an eight-inch reflector. I want to emphasize what he said about the necessity of having a short focus. I do not use a six-inch focus, but think an eight-inch focus essential for ordinary work. It should be remembered that the distance from the eye to the larynx is eleven inches in ordinary cases, and we have to use a reflector of eight-inch focus in order to concentrate divergent rays on the larynx. In using an ordinary light we must have this short focus. In using condensers it is better to have the lens and light so set that the rays are divergent, so that the same focal distance can be used. For daylight or parallel rays the focal distance of the reflector should be ten or eleven inches. With a three and one half inch or four-inch reflector it is quite important that the ball for the ball-and-socket joint should be only an inch and three-eighths from the center of the opening. In many that are sold it is two inches or more. The forceps for removing adenoids is essentially the same that I have used for fifteen or twenty years in removing masses of the adenoids from the choanæ, but I do not use them for the whole adenoid. I use MacKenzie's modification of Löwenberg's forceps. Dr. Barnhill suggests that with an ordinary adenotome Luschka's tonsil can be taken out with one sweep. A part of it can, but I think that the reason that there are 25 per cent. of recurrences is that the gland is not thus thoroughly removed. With this instrument the glandular tissue in the fossa of Rosenmüller is not taken out, and any portion pressing forward into the choana is also left. The forceps passed through the nose readily removes this mass and dilates any constriction of the choana. I once operated on a child, said to have adenoids, that had already been operated on by others three times for this condition. I found no adenoids but the choanæ were closed. Former operators had evidently confined themselves to scraping the nasopharynx. I had a little chisel made for operating on the septum, with a small guard that projects about 5 mm. from one side. This is about 1.5 mm. in diameter and has a small knob on the end designed to work under the mucous membranes without allowing the chisel to cut them. I have found this chisel especially useful in opening the sphenoid. The projecting guard is so small that it will readily enter the opening of the sphenoid cell and it can easily be directed with the finger in the nasopharynx when the patient is under an anesthetic. This prevents the chisel from slipping or cutting too far back and thus enables one quickly to cut away the front wall and the sphenoid cell so that any of the instruments designed for enlarging the opening may be introduced.

Dr. Otto T. Freer, Chicago: In an article read before the American Laryngological Association in 1906 and published in its transactions and the Annals of Otology, December, 1906, I fully explained the efficiency of my pernasal forceps and the ring knife. I regard the certainty of removing all of the adenoid tissue, no matter where located, in the posterior nares or nasopharynx as the chief merit of the forceps. In contrast to their thorough work the ring knife or curette in its endless forms is very apt to do an incomplete operation. I have repeatedly employed my forceps for the removal of adenoid masses which had been left behind after curettement by operators of experience and reputation. The forceps referred to by Dr. Ingals is the Ingals nasal bone forceps. It was the prototype of the pernasal forceps which I now employ, which, however, I have changed materially in form in order to adapt it to the removal of adenoid growths. Dr. Ingals spoke of his nasal bone forceps in his clinics as passed by him through the children's noses mainly in order to dilate the posterior nares but also for the purpose of removing fragments of the adenoid growths, which the Löwenberg forceps, employed postnasally by Dr. Ingals as his chief implement for the operation, had failed to take away. I regard myself as justified in claiming to be the originator of the idea of removing all of the adenoid vegetations pernasally by forceps, for which purpose I at first used the Ingals nasal bone forceps and later my present pattern of pernasal adenoid forceps, which seem to me much better suited for the purpose. The straight route through the nose employed in the operation is the one employed by Wilhelm Meyer, and its advantages lie in the greater precision obtained in operating with a straight instrument without confusing curves and in the thoroughness with which the work can be done because of the guiding presence of the index finger of the left hand in the nasopharynx, which indicates every vestige of the growths by the sense of touch and in addition protects the tubal prominences and lateral walls of the nasopharynx from injury. Adenoid masses in the fossa of Rosenmüller and posterior nares, inaccessible to the curette can be readily plucked away with the forceps. I know that the short-focus head mirrors are nothing new. Nevertheless, for some reason they have disappeared from the shops and a mirror of long focus, about fourteen inches, is the only thing obtainable and, while suitable for laryngeal work, it does not permit sufficiently close vision for the nose and ear, so I had a short-focus reflector made for that purpose. I use the Kirstein head lamp nearly exclusively in my work and hardly ever employ a head mirror.

Therapeutics

CROTON OIL.

Oleum tiglii, U. S. P. (genitive, olei tiglii), is a yellow, somewhat viscid, fixed oil, expressed from the seeds of the fruit of a small tree which grows in Southern Asia and the Philippine Islands. The seeds contain from 30 to 40 per cent. of this oil. The oil contains glycerides of various fatty acids, crotonol (the vesicating croton resin), and crotonolic (or crotonoleic) acid (closely allied to oleic and recinoleic acid). The croton resin is soluble in alcohol.

Croton oil is burning and acrid in taste, and an irritant to the skin and mucous membranes. On the skin it produces redness, papules passing into vesicles, and finally into pustules, which in healing leave white scars. Croton oil has been classed, for this action on the skin, as a "pustulent." Occasionally it may cause a general eruption resembling smallpox. Sometimes enough has been absorbed from the skin to cause purging.

When taken internally, unless very dilute, it is irritant to the stomach and intestines. It congests the mucous membrane of the intestines and increases peristalsis, causing copious stools accompanied by griping pains and a good deal of burning and irritation of the rectum and anus. It acts rapidly, a drop or two on the tongue causing a stool in one or two hours.

Large doses cause violent purging, griping, vomiting and collapse, and a few drops have been known to cause death. If it has been taken by mistake, a quickly acting emetic is indicated, with later mucilaginous, soothing drinks and a hypodermatic dose of morphin. If it has been in the stomach long enough to cause severe purging, the treatment is that of acute enteritis, and the collapse should be treated as usual, with external heat and cardiac stimulants.

Croton oil is used when a quickly acting cathartic is indicated, especially when there is difficulty in causing the patient to swallow, and a rectal injection of a cathartic is inefficient or too slow. Consequently, croton oil is used in uremia and in the coma of apoplexy where it is deemed advisable to reduce the blood pressure by purgation. It has been used in the constipation of lead poisoning and in other obstinate constipation, but it should be used with great care lest intestinal obstruction be present. It may be used at times in the constipation of maniacal patients who refuse to take other medicine, as the dose of this is so small it can be more readily administered.

Croton oil may be used externally as a counterirritant, and has been used for this purpose on the chest in various conditions, such as bronchitis, the dry pleurisies of phthisis, and as a counterirritant over the course of a painful nerve. However, it is now rarely used externally, other counterirritants being better and their activities being better controlled. To do any good, croton oil must be used in considerable strength, and then the pustulations are rather beyond control and the scars caused by such pustulation are objectionable. If it is used externally it should be diluted with two or three parts of a bland oil.

The dose of croton oil is one or two drops, and is well administered in a bread pill, made at the time, if the patient is able to swallow. If the patient can not swallow, a drop or two may be put on a little granulated sugar and this put into the patient's mouth, or, if necessary, a single drop may be placed on the back of the tongue. In conditions in which it is indicated a drop may be repeated every hour for several doses until purging takes place. It will rarely take more than two or three doses. Minute doses of croton oil are sometimes added to laxative pills to make them more active. This is inadvisable, however, as the tendency, as previously stated, of irritant cathartics to either cause inflammation of the intestines or at least increase the tendency to constipation should preclude their use.

Croton oil should not be administered to children, to debilitated patients, or to pregnant women except in desperate cases of uremic poisoning. Also gastrointestinal inflammation or peritonitis should prohibit its use.

GRUELS.

As this is the season for intestinal disturbances, the medicinal and hygienic treatment of such disturbances can not be dissociated from the feeding and nutrition. Consequently a few suggestions from the book by Alida F. Pattee may not be amiss.

FLOUR GRUEL.

Milk	1 cup.
Flour	½ tablespoonful
Salt	a speck
Raisins	1 dozen

"Scald the milk, mix the flour with a little cold milk and stir into the scalding milk. Cook in a double boiler for one-half hour or on back of stove in a saucepan. Stone and quarter the raisins, then add water enough to cover; cook slowly until the water has all boiled away; add to gruel just before serving, or eat with the raisins as desired. If there is much diarrhea the raisins should be left out."

BARLEY GRUEL.

Barley flour	2 tablespoonfuls
Milk, scalded	1 quart
Salt.	

"Blend the barley flour with a little cold milk and stir into the scalding milk. Cook in a double boiler two hours, salt to taste, and add sugar if desired; strain."

BARLEY GRUEL WITH BROTH.

Beef broth	2 cups
Barley flour	2 tablespoonfuls
Cold water	2 tablespoonfuls
Salt	1 saltspoonful

"Mix barley flour and salt with the cold water to form a smooth paste. Add gradually to the boiling stock and boil one-half hour. Strain and serve very hot.

EGG AND SHERRY GRUEL.

Egg	1
Sherry	1 wineglassful
Lemon juice	1 teaspoonful
Sugar	1 tablespoonful
Grated nutmeg.	
Smooth hot gruel	1 cup

"Beat the egg, add wine, lemon juice and nutmeg, and pour on the hot gruel."

ARROWROOT GRUEL.

Arrowroot	2 teaspoonfuls
Cold water	2 tablespoonfuls
Boiling water or milk	1 cup
Salt.	
Sugar, lemon juice, wine or brandy as required.	

"Blend the arrowroot and cold water to a smooth paste, add boiling water or milk and cook in a double boiler for two hours. Add salt, strain, and serve hot."

Both the barley and arrowroot may be administered in diarrhea.

INDIAN MEAL GRUEL.

Indian meal	1 tablespoonful
Flour	½ tablespoonful
Salt	¼ teaspoonful
Cold water	2 tablespoonfuls
Boiling water	1½ cups
Milk or cream.	

"Blend the meal, flour and salt with the cold water to make a smooth paste and stir into the boiling water. Boil on back of stove one and one-half hours, dilute with milk or cream, strain."

RICE GRUEL.

Rice flour	1 tablespoonful
Cold water	2 tablespoonfuls
Boiling water	1 quart
Salt.	

"Mix the rice flour with a little cold water to form a smooth paste, add the boiling water, and cook in a double boiler until transparent and thoroughly cooked. Add salt to taste, sweeten, and add milk if desired; strain."

OATMEAL GRUEL.

Coarse meal	¼ cup
Salt	½ teaspoonful
Boiling water	1½ cups
Milk or cream	

"Add oatmeal and salt to the boiling water, cook four or five hours in a double boiler, adding more water if necessary. Strain, and dilute with hot milk to make it of the right consistency. Re-heat and serve. Sugar and a little port wine may be added if desired."

FARINA GRUEL.

Farina	1 tablespoonful
Cold water	1 tablespoonful
Boiling water	1 cup
Scalded milk	1 cup
Salt.	

"Mix the farina with the cold water, add to the boiling water and boil thirty minutes. Add the scalding milk, taste and season properly. A little sugar may be added if desired, or an egg may be beaten and the gruel added to it."

BROWNED FLOUR GRUEL.

"Tie one-fourth pound of wheat flour into a thick cloth and boil it in a quart of water for three hours. Remove the cloth and expose the flour to the air, or heat it until it is hard. Grate from it when wanted a tablespoonful, put into a half pint of new milk, and stir over the fire until it comes to a boil, add a pinch of salt and a tablespoonful of cold water, and serve. This gruel is excellent for children with simple diarrhea."

FOR TOOTHACHE.

The *Druggists Circular*, March, 1908, gives the following suggestions for applications for toothache:

℞.	c c.		
Creasoti,			
Chloroformi,			
Olei caryophylli,		or	
Olei menthæ piperitæ,			
Olei camphoræ,			
Phenolis liquefacti, āā	5		āā, flʒi

M. et sig: Apply on cotton or pledgets of felt

Or,

℞.	gm. or c.c.		
Phenolis liquefacti	5		flʒii
Camphoræ	10	or	℥ss
Chloroformi	25		fl℥i
Olei cajuputi, q. s. ad	30		ad, fl℥ii

M. et sig: Apply on cotton or pledgets of felt.

Or,

℞.	gm or c.c.		
Phenolis liquefacti	60		fl℥ii
Mentholis,		or	
Thymolis,			āā, gr. xv
Collodii, āā	1		m. xv

M. et sig.: Jelly for toothache.

Or,

℞.	gm. or c c.		
Phenolis liquefacti	3		m. xlv
Capsici,			
Pulveris opii, āā	4	or	āā, ʒi
Olei caryophylli	8		flʒii
Chloroformi	75		fl℥iiss

M. et sig: Toothache tincture.

FOR LOCAL SWEATING IN TUBERCULOSIS

℞.	gm or c c.		
Mentholis	2		ʒss
Acidi salicylici	4	or	ʒi
Spiritus lavendulæ	200		fl℥vi

M. et sig.: Sponge the affected regions with the solution.

SUICIDE AND PROPHYLAXIS

In recent years the problem of suicide has come to be looked on as a medical question, and this makes for real understanding of the situation as well as furnishing the best possible hope of its amelioration. It becomes important under these circumstances for the physician to know just what the situation with regard to suicide in this country is. In a recent article Mr. George Kennan[1] has collected some valuable statistics that are probably the most authoritative figures on the subject at present obtainable and which, therefore, deserve consideration. Our annual suicide loss is enormous, for, according to Kennan, we are losing every year from this cause more than were killed on the Union side in the three great battles of Gettysburg, Spottsylvania and the Wilderness taken together.

The serious phase is that for twenty-five years the annual suicide rate has increased with large strides. In 1881 the rate in the United States was but 12 per 1 000 000 of the population and our total number of suicides in the whole country was only 605. Last year it had risen to 126 per 1 000 000 and our suicides numbered 10,782. If the present rate of increase be maintained—and there seems to be no reason that it should not be—we shall lose by suicide in the next five years nearly as many lives as were lost by the Union armies in battle in the five years of the Civil War. Since 1890 suicide has cost the United States over 120 000 lives. It is true that European countries have lost even more than we have, but far from being encouraging, this only adds to the blackness of the situation.

Certain features of the suicide situation deserve special attention. It has been asserted that the depression which accompanies dark days or prolonged periods of lack of sunshine is responsible for many self-murders. Three of the best authorities on the subject, however—Dr. Geck of Strasburg, who collected the statistics of about 100 000 suicides that took place in Prussia in the twenty years from 1876 to 1896, Durkheim of Paris and Dr. Gubski of St. Petersburg, who have investigated the subject more recently for the whole of Europe—assert that suicides invariably attain their maximum in June and their minimum in December. Geck found a constant rise in the suicide curve from January to the end of June and a constant decline from June to the end of the first winter month. This does not mean, however, that climate is as important an element in suicide as it might seem to be, for it is not in the torrid zone but in the temperate zone that the highest suicide rate is reached. The maximum of 172 suicides annually to each 1,000 000 of inhabitants occurs between the parallels of latitude 50 and 55 in the north temperate zone—that is, just where climate is most salubrious and least annoying.

Perhaps the most interesting phase of this question of the relation of the weather to suicide is that advanced by Prof. Edwin G. Dexter.[2] He found by a comparison between the dates of nearly 2,000 cases in the city of New York and the records of the New York weather bureau on the days for which these suicides occurred, that not only is the tendency to suicide greatest in the spring and summer months, "but it is most marked on the clearest, sunniest and pleasantest days of these months. The clear dry days show the greatest number of suicides and the wet partly cloudy days the least, and with differences too great to be attributed to accident or chance."

One other curious feature is that in times of stress the suicide rate always drops. During war time suicides are much less frequent than in peace. Other forms of stress, however, have the same favorable influence. Before the earthquake at San Francisco the suicides of that city averaged twelve a week. After the earthquake, when the whole population was homeless, destitute and exposed to hardships of every kind, there were only three suicides in three months. The decrease in the suicide rate was more than 97 per cent.

The all-important question for us is, What can be done to prevent the further increase of suicide? There are probably only two remedies practically available. The most important of these is undoubtedly the prohibition of the publication of the details of suicides, for this inevitably tends to suggest to certain weaker minds the imitation of the act described. This influence of suggestion due to the reading of the details of suicides is now generally recognized by those who have studied the question most and we feel sure is much more important than is sometimes thought. We unhesitatingly say that at least one-third of all suicides have some imitative element in them. Hence if we could secure the absolute prohibition of the publication of suicide details—the fact but not the manner might still be reported—and in addition could make it generally understood that suicide is a disease to be prevented and not a crime to be condoned or condemned, we doubtless would be able to do much to reduce the appalling increase in the suicide rate which is such a lamentable blot on recent social statistics.

RELATION OF EDUCATION TO PREVENTIVE MEDICINE.

The triumphs of preventive medicine are a matter of just pride to the medical profession. But while we may congratulate ourselves on what has already been accomplished, we must admit that much remains to be done. Considered in the light of what is possible, that which has been done is so far behind what might have been done as to constitute after all an occasion rather for regret, coupled with a stimulus to renewed and greater effort, than for self-gratulation.

This aspect of the question is emphasized by an extensive monograph by Dr. N. E. Ditman[1] on "Education and Its Economic Value in the Field of Preventive Medicine," in which he urges the need of a school of sanitary science and public health. The present problems of the public health and of sanitary administration involve much more than a knowledge of bacteriology or the physical causes of disease. Politics, sociology and morality are all concerned. Effective measures for removing the causes of disease can be carried out only with the support of an enlightened public opinion, and this must be formed by education. As the activities of the physician — the natural educator of the public in such matters — have heretofore been directed mainly along the lines of curative medicine, he is often ill-prepared for the new duties thrust on him by the demands of modern sanitation. This education of the public, to be efficient, will necessitate in many instances a postgraduate education of the practicing physician, and also provision for a training of the medical student in sanitary science superior to that hitherto in vogue.

As for specialization in sanitary work among the members of the medical profession, the time must come when one who undertakes the functions of a health officer will be required to show evidence, either in the form of a diploma or otherwise, of special training. In Great Britain such diplomas have now for some years been granted by nearly all the universities and are an essential prerequisite, in most instances, for appointment as medical officer of health; nor is Great Britain alone in this. Some such qualification should be required here. Again, teachers in public schools and higher institutions of learning have excellent opportunities for imparting instruction regarding health and its relation to economics and social problems, and they must form an important agency in securing the proper basis for efficient sanitary action by public officials. It is vastly important, therefore, that all these classes should receive appropriate training. This can best be afforded by a school whose instructors are in close touch with the methods and aims of sanitation as represented by the advanced thought of the medical profession.

Philanthropic and social workers also need such an education, while the ministry, the legal profession, the prospective statesman and the public in general should all receive instruction, suited to their respective needs, concerning the varied relations of disease to morals, crime, poverty, and economic questions. The needs of this class could be adequately met by special courses of instruction, both at the proposed school and in other large centers by lecturers appointed by, and under the control of, the school.

Ditman suggests that such a school should be in connection with a university having a well-equipped medical department and ample opportunities for scientific demonstration and research. It should be situated in a large city to afford practical illustrations of health department methods and of the various forms of unsanitary environment. It should provide a wide range of courses suited to the needs of its various classes of students, certain of which courses might well be required of applicants for a degree in the university. Ditman gives a list of thirty-five subjects adapted to this end, and the number of courses might easily be multiplied.

The great value of such a school will readily be admitted. There are opportunities for the establishment of several such in the United States. The economic results of the reduction of sickness and death thus made possible ought to be sufficient reason for establishing them, not to mention the higher interests served by the alleviation of suffering and the promotion of morality.

NATIONAL DEPARTMENT OF PUBLIC HEALTH.

The Democratic National Convention adopted a plank in its platform endorsing the organization of all existing national public health agencies into a national bureau of public health. The Republican National Convention adopted a similar, but less specific plank on the same subject. With both of the leading political parties committed by their platform declarations to advance legislation along sanitary lines, there should be no difficulty in securing the introduction and consideration of a bill in Congress in the near future for an adequate national health bureau or department.

Recent advances in scientific medicine; public recognition of sanitary victories, such as the stamping out of yellow fever in New Orleans and Havana and the suppression of the bubonic plague in San Francisco; greatly increased public interest in health matters, as shown by the successful campaigns for pure food and against dangerous drugs; the increasing desire of the people for trustworthy information on all health topics, as shown by recent articles in the popular magazines, all combined with the epoch-making reorganization of the medical profession, unite to form an incentive to a popular movement for a national health organization such as has not heretofore been possible. The exact manner of organization, whether as a bureau or as a department; the question of a cabinet officer versus a bureau chief; the alternatives of the immediate organization of a new department or the gradual expansion of existing bureaus, all are subordinate to the general purpose of such a movement—the conservation of the lives and health of the people. The time is ripe for action, and the people are ready to support the movement.

---

[1] Columbia University Quarterly, June, 1908, x, No. 3, supplement.

To be successful, however, there must first be a careful study of all the conditions involved. It is no credit to our profession that we frequently approach legislators, urging the adoption of bills that are hastily and carelessly prepared without adequate understanding of the problems involved or of laws already existing. It sometimes happens, too, that a bill as drafted represents the prejudices or personal views of one or two men rather than the accumulated experience of the entire profession. It is time for us to realize that if we wish to be recognized as having a right to participate in law making and governing we must show ourselves worthy of such privileges. If we wish the support of law makers and law administrators, we must show that we can draft sound laws on broad principles. A bill for the establishment of a national department of health should not be drawn until accurate knowledge has been obtained regarding all national health agencies now existing, not only in this but in other countries. The practical and legal relations now existing between present health agencies, both state and national, should also be carefully studied, as well as the relation which the proposed bureau will bear to all our other executive and administrative departments. The cooperation of all existing public health and sanitary forces should, so far as possible, be enlisted. Above all, personal prejudices and animosities should be entirely discarded and the health of the public should be considered above all else.

If wisdom and tolerance be observed and careful investigation and public education precede the presentation of the bill, it will have the support of all parties and of all factions. An unprecedented opportunity now presents itself for the profession to show a spirit of broad and constructive statesmanship.

NOTABLE ANTITUBERCULOSIS LEGISLATION.

New York State has just passed a law declaring tuberculosis to be an infectious and communicable disease and providing for the reporting of all cases to the local health authorities. Its salient features comprise the free examination of sputum by the health authorities in all suspected cases; registration and the inviolability of all such records; the disinfection and renovation of premises after the death or removal of a consumptive, and the rendering innocuous of all tuberculous sputum. The physician must send to the health officer of his community a statement of the precautions he takes in a case of this disease; he must safeguard in every reasonable way those living in the same house with the consumptive patient; and for his report he receives a fee of $1.00. Should the physician fail to report, this duty devolves on the health officer, who will then receive the fee. Penalties[1] are imposed on physicians and others who fail to execute the duties required by this act.

All the measures incorporated in this law have become commonplaces of sanitary requirement, and they well epitomize the essential prophylaxis against tuberculosis. A positive finding in sputum examination places the diagnosis of the disease beyond question, but surely no physician will to-day wait for such evidence before reaching a conclusion. The disease has usually passed well beyond incipiency before bacilli are discoverable in the sputum. Of all the steps toward communal protection registration is by far the most important; no adequate disinfection or renovation of premises is possible otherwise.

This New York state law was signed at about the same time as a similar statute for the District of Columbia to which the President has affixed his signature. In preparing the New York law those now in operation in Vermont, New Hampshire and Wisconsin were carefully considered; much was derived from them, from the sanitary code of New York City, and from the new federal law. A wise disposition is here being shown by government and humanitarian bodies to make observations and concessions, dictated, as Secretary Root notes, "by enlightened judgment for the common benefit." We may confidently hope that all our states will presently have similar statutes in force.

THE HEALING OF EXPERIMENTAL TUMORS BY TRANSFUSION OF BLOOD.

There occurs occasionally on the generative organs of dogs, and transmitted by coitus, a peculiar form of tumor that is generally designated as a lymphosarcoma, but concerning the actual nature of which there has been some difference of opinion. The readiness with which it can be transplanted from dog to dog, either experimentally or through coitus, makes it seem much more like an infective granuloma than like the true malignant tumors; but most of the more recent observations seem to indicate that this growth really is a lymphosarcoma which, as the result of repeated natural implantation through coitus, has become adapted in a high degree to this method of propagation. Although this is merely a canine disease, yet its proper classification becomes an important matter because of the use to which it is being put in connection with the experimental study of tumors, along with the transplantable carcinomas of mice and sarcomas of rats. The newest observations on the transplantable lymphosarcoma of dogs, by Crile and Beebe, are of particular interest because they demonstrate a method by which these growths can be made to disappear and leave the animal immune and well.

All the transplantable tumors so far studied in laboratory animals show a tendency to spontaneous retrogression, which feature might seem to indicate that they are essentially different from the malignant tumors occurring in man which are remarkable rather for the absence of any such desirable tendencies. However, this difference is perhaps rather apparent than real, depending on the fact that spontaneous tumors developing in man appear only in individuals in whom conditions favor the formation of neoplasms, while in the experimental tumors inoculations are made into normal animals that are entirely free from any such tendency to tumor formation, and which are possessed of a certain degree of natural immunity.

---

[1] THE JOURNAL A. M. A., May 30, 1908, p. 1804.

Be that as it may, it is an important fact that animals thus recovering spontaneously are immune to further inoculation with tumors, and their blood contains substances which inhibit tumor growths; these observations made by Gaylord and Clowes, and at first disputed by Bashford and Ehrlich, are now generally accepted in view of their abundant corroboration. Basing their experiments on these facts, Crile and Beebe[1] found that if an animal with progressing tumors were bled freely and then transfused with a considerably larger amount of blood from a dog immune to such tumors, the growth of the tumors was usually checked and they soon underwent complete absorption. These results were much the same whether the immunity of the dog furnishing the blood was evidenced by an insusceptibility to inoculation with tumors or was an acquired immunity manifesting itself by spontaneous retrogression of tumors that had been growing for a time. The authors consider that immunity to tumors is not strictly analogous to bacterial immunity. Nevertheless their results show that it is to some extent a blood condition which may be transferred to another animal, rendering it passively immune.

Interesting and suggestive as these experiments are, Crile and Beebe wisely refrain from any premature speculation as to their application to the treatment of human tumors, a subject that must be first approached only after a more extensive experience with animals has been obtained.

THE INDEX TO CURRENT LITERATURE.

When, in our issue for June 27, we appealed to our readers for an expression of their views with reference to the continuance of the Index to Current Medical Literature we realized that we were asking a good deal, in view of the season of the year and other factors, in calling for at least 500 replies. So also, apparently, thought many of those who wrote promptly in their anxiety to avert a threatened discontinuance, for they begged us to be content with less than the specified number of replies. It is, however, most gratifying to learn that the appreciation of the labor involved in the Index to Current Medical Literature is both widespread and deep. The number of those who have responded to date is 586—and communications are coming in every mail—and of these only nine appear indifferent or half-hearted. Practically all beg us not to think of discontinuing the index, which large numbers seem to consider almost, if not quite, the most valuable feature of The Journal. This hearty response, moreover, besides effecting its purpose of dispelling any idea of abandoning the Index to Current Medical Literature, has had the effect also of stimulating to greater effort that portion of the editorial staff on whom the responsibility and labor fall. We thank most heartily all those who have replied to our questions, especially those who have offered suggestions for improvement. These suggestions are being carefully considered, and we assure our readers that if any change is made it will be toward making the index more useful and more practical.

MEDICAL COLLEGE MERGERS.

Last week we announced the merger at Cincinnati of the Miami Medical College and the Medical College of Ohio which promises so much for the future of medical education in that city and state. This is the eleventh merger of medical colleges which has taken place in less than three years, during which time twenty-three of these institutions have united their forces, leaving nine larger and stronger ones. In Indiana five colleges have finally been welded into one, in Kansas four were merged into one, and in Kentucky four into two, while in Missouri, in Ohio at Columbus, in Minnesota, and now again in Ohio at Cincinnati, two colleges in each instance merged into one. In every instance these mergers have registered a desire on the part of the faculties for higher educational standards, and the manner in which personal interests have been set aside that better institutions might result has revealed a magnanimity, an unselfishness and a public spirit that are most encouraging and commendable. It is this spirit which shows that the medical profession of this country will not be content until medical education in the United States is second to that of no other nation. There remain several other cities having from two to five separate colleges where mergers similar to the above are being contemplated. In some of these a strong public spirit already prevails and positive action will not be long withheld. It is evident that the merging of our numerous small and poorly equipped medical colleges into a less number of well-equipped and strong institutions is the most encouraging part of the movement for higher standards of medical education in the United States.

Hot Horse Serum in Treatment of Burns.—R. Petit's communications on the efficacy of hot horse serum in local treatment of wounds have been summarized in these columns from time to time. He now announces that it is proving the best topical application for extensive burns. The *Presse Médicale*, June 13, quotes some of his case histories, showing that healing was much more rapid in the burns treated with the hot horse serum than in other burned patches on the same child treated with picric or boric acids, etc. He believes that the horse serum revives the injured cells, possibly including the nerve cells, so that they recuperate and aid in the healing process, instead of dying and generating poisons. The serum also summons the leucocytes to the spot, while its harmlessness has been demonstrated.

Medical News

ILLINOIS.

Free Treatment of Hydrophobia.—Dr. J. A. Egan, secretary of the Illinois State Board of Health, requests us to announce, for the information of physicians and health officers, that in 1905 the General Assembly made provision for the care and treatment of poor persons duly certified by regular physicians to have been bitten by rabid animals, or otherwise put in danger of infection from hydrophobia, and that such persons unable to pay for treatment themselves will be cared for at the expense of the state, at the Pasteur Institute, 228 Dearborn Avenue, Chicago, the institution selected by the Illinois State Board of Health.

Chicago.

Medical College in Good Standing.—We are informed by the Illinois State Board of Health that owing to a clerical error, the College of Medicine and Surgery, Physio Medical, was omitted from the list of colleges in good standing, sent to us last week.

Chicago's Health.—According to the bulletin of the Chicago Department of Health, the city's health was never better than during the week ended July 11. The average death rate of the last ten years was 14.21 per thousand, the rate of the first eleven days of the present month was 10.88. Had the average rate of previous years obtained there would have been 928 deaths during the eleven days instead of the 710 which did occur. To the total of 510 deaths reported during the week ended July 11, violence contributed 62—a greater number than any of the diseases, consumption was second in order of highest mortality, with 57 deaths, the diarrheal diseases, 52, nephritis, 42, heart diseases, 40, pneumonia, 36, cancer and the nervous diseases, each 28. There was but one death from typhoid fever reported, as against 7 in the week preceding and 5 in the corresponding week of last year. A death from tetanus was recorded during the week, but not due to a Fourth of July injury.

Mortality of Chicago During the First Half of 1908.—According to the statistics of the Department of Health, 1,998 fewer people died during the first six months of 1908 than during the corresponding period of last year. The diseases in which the greatest improvements in the mortality rate is shown are pneumonia and pulmonary tuberculosis, the actual decrease in the number of deaths from pneumonia is 949, from tuberculosis is 174. On the other hand, deaths from diarrheal diseases in children have increased, especially in children under one year, the increase over last year being 183. June had the very low general death rate of 11.77 per thousand of population. This is 6.5 per cent. lower than the ten year average for June and 13.4 lower than June, 1907. In the last fifty years there have been but two Junes with a lower rate. The total deaths reported during the month—2,095—were 348 fewer than the preceding month and 260 less than the returns of June, 1907. Of the diseases which show the greatest reduction, pneumonia leads, with 103 fewer deaths than the preceding month and 133 fewer than the corresponding month of last year. There were 24 fewer deaths from consumption than in the preceding month and 12 fewer than the compared period of 1907. The reduction in contagious diseases similarly compared was 27 and 42. A marked increase is noted in deaths from diarrheal diseases. The 153 deaths reported during the month exceed the preceding month by 22 and the corresponding month of last year by 38.

INDIANA.

Sex Relation and Social Hygiene.—At a recent meeting of Marion County Medical Society, resolutions were adopted, setting forth that it would be wise to teach young people, with seriousness and dignity, the facts about reproduction and the almost certain evil effects of unchastity.

Itinerant Physicians.—The common council of Logansport has passed an ordinance providing for a license fee of $50 per day for itinerant physicians or traveling vendors of drugs or remedies, the violation of the ordinance to bear a penalty or fine not less than $50 nor more than $100 for the first offense, and for not less than $50 nor more than $300 for each subsequent violation.

Officers and Faculty of Medical School.—At a meeting of the board of trustees of the Indiana University, held in Bloomington June 23, the following officers and faculty for the school of medicine were selected: Dr. Allison Maxwell, dean; Dr. Edward F. Hodges, vice dean; Dr. Edmund D. Clark, secretary, Dr. John S. Barnhill, treasurer, and B. D. Meyer, secretary of the medical department. Drs. Henry Jameson, Allison Maxwell and George W. McCaskey, professors of medicine, Drs. Louis Burkhart, Samuel E. Earp, George D. Kahlo, Theodore Potter, and Albert C. Kimberlin, clinical professors of medicine, Drs. Francis D. Dorsey and Robert H. Ritter, associate professors of medicine; Dr. Frank B. Wynn, professor of medical diagnosis; Dr. William T. S. Dodds, associate professor of clinical diagnosis; Dr. Simon P. Shearer, professor of gastrointestinal diseases; Dr. L. Park Daryer, professor of pediatrics; Drs. James H. Taylor and John A. Lambert, clinical professors of pediatrics; Dr. Amelia R. Keller and Dr. Oscar N. Torian, associate professors of pediatrics; Drs. Frank F. Hutchins, Ernest C. Reyer and Albert E. Sterne, professors of mental and nervous diseases, Drs. Charles S. Neu and Robert N. Todd, associate professors of nervous and mental diseases, Drs. William H. Foreman and C. Richard Schaefer, professors of therapeutics; Dr. Thomas W. Haas, associate professor of therapeutics, Dr. John N. Hurty, professor of hygiene and sanitary science; Dr. Samuel C. Norris, associate professor of hygiene and sanitary science; Drs. James H. Ford, John H. Oliver and Miles F. Porter, professors of surgery, Drs. Edmund D. Clark, J. Rilus Eastman and George M. Wells, professors of clinical surgery; Drs. Maynard A. Austen and David Ross, associate professors of surgery; Dr. Horace R. Allen, professor of orthopedic surgery; Drs. William N. Wishard and John A. Sutcliffe, professors of genitourinary surgery; Drs. Frederic R. Charlton and Harvey A. Moore, clinical professors of genitourinary surgery; Drs. George J. Cook and John C. Sexton, professors of gastrointestinal surgery, Drs. Alois D. Graham and Thomas C. Kennedy, clinical professors of gastrointestinal surgery; Drs. Walter S. Given and Homer H. Wheeler, associate professors of gastrointestinal surgery, Dr. Alembert W. Brayton, professor of dermatology and syphilology; Drs. Albert M. Cole and E. Oscar Lindermuth, professors of electrotherapeutics and dermatology, Drs. Albert E. Bulson, Thomas C. Hood and Frank A. Morrison, professors of ophthalmology; Drs. Harry C. Parker and Frederic C. Heath, clinical professors of ophthalmology; Drs. John S. Barnhill, Lewis C. Cline, John J. Kyle, and Kemp K. Wheelock, professors of otology, laryngology and rhinology; Drs. John L. Masters, Lafayette Page and Ernest DeW. Wales, clinical professors of otology, laryngology and rhinology; Dr. Orange G. Pfaff, professor of gynecology; Drs. Thomas E. Eastman, Thomas B. Noble and Hugo Pantzer, clinical professors of gynecology; Drs. Bernays Kennedy and Robert O. McAlexander, associate professors of gynecology, Drs. John T. Davis, Sidney J. Hatfield, David Tahn, Goethe Link, and John Pfaff, associate professors of gynecology; Dr. Edward F. Hodges, professor of obstetrics; Dr. Charles E. Ferguson, clinical professor of obstetrics; Dr. Henry F. Beckman, associate professor of obstetrics; Dr. Charles S. Neu, professor of pathology; Dr. John W. Fluss, professor of anatomy; Drs. John Morris, Norman E. Jones, Walter W. Barnett, W. B. Robinson, and Charles O. Durham, associate professors of anatomy, Drs. Gustave A. Petersdorf and Charles S. Woods, professors of chemistry, and Dr. William O. Gross, professor of toxicology.

IOWA.

Personal.—Dr. H. J. James, formerly assistant physician at Muskoka Cottage Sanatorium, Canada, has been appointed assistant superintendent at the State Sanatorium for Tuberculosis, Oakdale.

Epidemic Diseases.—An epidemic of German measles is reported from Sloan.——Smallpox is reported to be prevalent in Washington Township, Atlantic County.——The secretary of the University Y. M. C. A., Iowa City, was stricken with smallpox, June 3. The building has been closed and fumigated.——Two cases of smallpox, said to be imported from Missouri, are reported in Davenport.——Rockwell City is reported to have 57 cases of typhoid fever, with 5 deaths.

Medical Society Meetings.—At the annual meeting of the Central Iowa Medical Association, held in Nevada, June 16, the following officers were elected: President, Dr. Alpheus A. Deering, Boone; vice president, Dr. John W. Bailey, Nevada, and secretary-treasurer, Dr. James C. Walker, Boone. The next meeting will be held at Boone.——At the semi annual meeting of the Iowa Union Medical Society, held in Iowa City June 23, the following officers were elected: President, Dr. L. Wallace Dean, Iowa City; vice president, Dr. William R. Whiteis, Iowa City, secretary, Dr. Alexander Crawford, Mount Vernon; treasurer, Dr. George P. Carpenter, Cedar

Rapids, and censors, Drs. Edwin Burd, Lisbon, John W. Lagrange, Marion, and Hollis W. Bender, Cedar Rapids. The next meeting of the society will be held in Cedar Rapids.——The thirty-seventh annual meeting of the Des Moines Valley Medical Association was held in Ottumwa June 18 and 19. The following officers were elected: President, Dr. Lewis A. Rodgers, Oskaloosa; vice-presidents, Drs. Frank T. Stevens, Mount Pleasant, and Charles B. Powell, Albia; secretary-treasurer, Dr. Fred W. Bowles, Ottumwa, and censors, Drs. Smith A. Spilman, Ottumwa, Henry C. Young, Bloomfield, and Clyde A. Boice, Washington. The next meeting will be held in Ottumwa.

MARYLAND.

Medical Student Dies Just Before Graduation.—William George Thomas died at Cumberland, Md., May 7, of tuberculosis, five days before his graduation from the Southwestern Homeopathic College, Louisville, aged 24.

Baltimore.

Personal.—Dr. Leo G. Scheurich, a recent graduate of the medical department of the University of Maryland, was given a banquet by the Holy Cross Lyceum and presented with a case of pocket instruments, July 9.——Dr. Cary B. Gamble has been appointed a member of the board of supervisors of city charities.——Dr. Henry Kenwood has gone to Bedford Springs, Pa., as resident physician for the season.——Dr. James H. Chestnutt of the Johns Hopkins Hospital staff was operated on for appendicitis July 10.——Former internes of the University Hospital have located as follows: Dr. G. W. Billupo, chief resident surgeon, Woman's Hospital, Baltimore; Dr. Joseph L. Valentini, Baltimore; Dr. Charles W. Roberts, southern Georgia; Dr. E. W. Glidden, Savannah, Ga.; Dr. Thomas Legg, western Maryland; Dr. Joseph A. Barry, New York; Dr. Salvador Giuliani, Viegues, Porto Rico; Dr. Rufus C. Franklin, Craymount, Ga.

MASSACHUSETTS.

Course in Psychotherapy.—Tufts Medical School announces it will add to its curriculum a course in psychotherapy, beginning October 1, in charge of Dr. Morton H. Prince and Rev. Albert E. Shields.

Alumni Meetings.—The fourth annual dinner and meeting of the New England Association of Jefferson Medical College Alumni was held in Boston, when Dr. John Q. A. McCollister, Waltham, of the class of 1856, was elected president; Dr. Angus McOdrum, Boston, of the class of 1889, secretary, and Dr. Henry J. Walcott, Concord, of the class of 1890, treasurer.——At the annual meeting of the Harvard Alumni Association, held June 23, Drs. Vincent Y. Bowditch, Boston, of the class of '79; Henry F. Lewis, Chicago, of the class of '88; and Malcolm Storer, Boston, of the class of '89, were elected to fill vacancies in the council.

Society Meetings.—At the annual meeting of the Barnstable District Medical Society at Hyannis, the following officers were elected: Dr. Stephen H. Sears, Yarmouth Port, president; Dr. Henry B. Hart, East Dennis, vice-president; Dr. John P. Nickerson, West Harwich, secretary; Dr. William D. Kinney, Osterville, treasurer; Dr. Ephraim Cutter, West Falmouth, librarian; and Dr. James H. Higgins, Marston's Mills, trial committee.——At the annual meeting of the Hampshire District Medical Society, held in Northampton, Dr. Worthington W. Miner, Ware, was elected president; Dr. Frank H. Smith, Hadley, vice-president; Dr. Arthur G. Minshall, Northampton, secretary; Dr. Alfred H. Headley, Northampton, treasurer; and Dr. Edward W. Brown, Northampton, librarian.——Worcester District Medical Society, at its annual meeting, elected the following officers: Dr. William G. Reed, Southbridge, president; Dr. Lemuel F. Woodward, Worcester, vice-president; Dr. George E. Emery, Worcester, secretary; Dr. George O. Ward, Worcester, treasurer; Dr. Michael F. Fallon, Worcester, orator; and Dr. Ernest V. Scribner, Worcester, commissioner of trials.——At the annual meeting of the Essex South District Medical Society, held in Salem the following officers were elected: Dr. Snow P. F. Cook, Gloucester, president; Dr. Frederic W. Baldwin, Danvers, vice-president; Dr. George K. Blair, Salem, secretary; Dr. George Z. Goodell, Salem, treasurer; Dr. Carolus M. Cobb, Lynn, librarian; and Dr. Ralph E. Bicknell, Swampscott, commissioner of trials.——At the meeting of the Bristol South District Medical Society, held in Fall River, the following officers were elected: Dr. William T. Learned, Fall River, president; Dr. Augustus H. Mandell, New Bedford, vice-president; Dr. Alanson J. Abbe, Fall River, secretary-treasurer; and Dr. George L. Richards, Fall River, commissioner of trials.——Franklin District Medical Society, at its annual meeting, held in Greenfield, reelected the following officers: Dr. John W. Cram, Colerain, president; Dr. Charles L. Upton, Shelburne Falls, vice-president; Dr. Clara M. Greenough, Greenfield, secretary-treasurer; and Dr. Frances E. Johnson, Erving, commissioner of trials.

MICHIGAN.

Antituberculosis Charity Fund.—As a result of contributions in Detroit on Tuberculosis Charity day, a grand total of $11.274.99 was received.

Graduating Exercises.—The graduating exercises of the American Medical Missionary College were held at the Battle Creek Sanitarium, June 17, when a class of four was graduated. The address to the graduating class was delivered by Rev. Robert H. Nassau, M.D., a veteran missionary from West Africa.

Isolation Hospital and Tuberculosis Sanatorium.—Work is soon to be commenced on the new Contagious Disease Hospital and Sanatorium for Tuberculosis, Detroit, a site having been selected on Hamilton boulevard. The tract contains 25 acres, and the plans call for a group of buildings for the care of acute contagious diseases and for a tuberculosis sanatorium.

The Lake Michigan Water Commission.—In The Journal, July 11, page 136, we stated erroneously that Dr. Oscar C. Breitenbach had been elected president of the Lake Michigan Water Commission. Dr. Breitenbach directs our attention to the mistake and states that he is president of the Michigan State Water Commission, a subcommittee to the other organization of which Dr. William Evans, Commissioner of Health, Chicago, is president.

MISSOURI.

State Board Election.—At the annual meeting of the State Board of Health, held in Springfield, the following officers were elected: Dr. Albert H. Hamel, De Soto, president; Dr. James A. B. Adcock, Warrensburg, secretary.

Society Meetings.—Macon County Medical Association, at its annual meeting, held in Macon, elected the following officers: Dr. P. S. Watson, president; Dr. Alfred B. Miller, Macon, vice-president; Dr. Daly, secretary, and William H. Miller, Macon, treasurer. The next meeting will be held in Keota.——At the annual meeting of the North Missouri Medical Society, held in Moberly, June 18 and 19, the following officers were elected: President, Dr. Edward A. Grum, Kirksville; vice-presidents, Drs. William L. Brosius, Gallatin, and Godfrey O. Cuppaidge, Moberly; corresponding secretary, E. C. Callison, Kirksville; recording secretary, Dr. Olion C. McEwen, Salisbury, and treasurer, Dr. Robert Haley, Brookfield.

St. Louis.

Personal.—Dr. Rodney J. Bunch has been appointed assistant superintendent of the City Hospital, vice Dr. J. Wilbur Shankland, resigned.——Drs. John W. Marchildon and R. L. Thompson have gone to Europe.

Graduation Exercises.—The degree of M.D. was conferred on a class of 60 at the commencement exercises of the Washington University Medical Department, May 25, by Marshall S. Snow, acting chancellor of the university.——Following the action of the State Board of Health in declaring the Medical Department of Barnes University an incomplete institution, permission was refused, June 1, to 75 members of the graduating class to take the state examination. At a meeting of the faculty of the college, it was decided to carry the controversy to the supreme court in a final endeavor to allow its graduates to take the state medical examination.——The seventy-ninth annual commencement exercises of the Medical Department of the St. Louis University were held May 22, when a class of 68 was graduated. Rev. J. P. Frieden, president of the university, delivered the commencement address.

NEBRASKA.

Commencement Exercises.—The sixty-first annual commencement exercises of the University of Nebraska College of Medicine were held in Omaha, May 21, when a class of 25 was graduated. The doctorate address was delivered by Dr. Harvey W. Wiley, director of the U. S. Bureau of Chemistry, Washington, D. C.

County Society Organized.—At a meeting of physicians of the county, held in Plainview, May 13, the Pierce County Medical Society was organized on the standard plan. The following officers were elected: President, Dr. James M. Alden, Pierce; vice-president, Dr. Frank H. Nye, Plainview; secretary-treasurer, Dr. Leon R. Pheasant, Pierce, and councilors, Drs. Erskine M. Barnes, Plainview, John T. Pringle, Pierce, and Mansen.

NEW JERSEY.

Charity Ball Receipts.—The recent charity ball at Trenton, it is reported, will net each of the three hospitals in the city $3,569.40.

Hospital Corps for National Guard.—In accordance with the provisions of the Dick bill, a hospital corps has been formed, the members of which will be borne on a separate muster roll prepared by the senior medical officer of the organization to which the individual members are assigned.

State Society Meeting.—At the one hundred and forty-second annual meeting of the Medical Society of New Jersey, held at Cape May, June 18-20, the following officers were elected: President, Dr. David St. John, Hackensack; vice-presidents, Drs. Benjamin A. Wadington, Salem, Thomas H. Mackenzie, Trenton, and Daniel Strock, Camden; corresponding secretary, Dr. Harry A. Stout, Wenonah; recording secretary, Dr. William J. Chandler, South Orange, and treasurer, Archibald Mercer, Newark. The committee on prize essays announced awards to Drs. Thomas N. Gray, East Orange, and Floyd McEwan, Newark, whose essays were on "Infant Feeding During the First Two Years of Life."

Health of New Jersey in June.—The number of deaths reported to the Bureau of Vital Statistics during the month ended June 15 was 2,628, an increase of 26 over the previous month and 77 less than the corresponding period last year. The deaths under one year numbered 444; over one year and under five years, 249; sixty years and over, 768. The number of deaths from typhoid fever (18) is lower than for any period during the last twelve months. During the month tuberculosis caused 353 deaths; diseases of nervous system, 345; diseases of circulatory system, 289; diseases of respiratory system (pneumonia excepted), 153; pneumonia, 218; nephritis, 190; diseases of digestive system (infantile diarrhea excepted), 159; cancer, 121; scarlet fever, 48; suicide, 42; infantile diarrhea, 66; diphtheria, 41; measles, 23; cerebrospinal meningitis, 22; whooping cough, 21; typhoid, 18; all other causes, 519.

NEW YORK.

Personal.—Dr. Charles Phillips Emerson, formerly of Baltimore, was inaugurated superintendent of Clifton Springs Sanitarium July 9.

New Hospital for Buffalo.—Owing to the lack of proper facilities for the care and treatment of contagious diseases, the Buffalo Academy of Medicine has appointed a committee to facilitate the building of a municipal hospital for contagious diseases. The Erie County Medical Society has likewise appointed a committee of fifteen to further this project.

Officers of the Buffalo Academy of Medicine.—At the annual meeting of this society officers were elected as follows: President, Dr. Charles Bowerman; secretary, Dr. William Irving Thornton; treasurer, Dr. Harry R. Trick; chairman of the section of medicine, Dr. Julius Ullman; secretary, Dr. Thomas J. Walsh; chairman of the section of surgery, Dr. Lawrence Hendee; secretary, Dr. Frederick J. Parmenter; chairman of the section of pathology, Dr. James A. Gibson; chairman of the section of obstetrics, Dr. Earl P. Lathrop; secretary, Dr. Edward Mann.

Day Camp for Consumptives.—Through the efforts of public-spirited citizens of Buffalo, an adequate sum has been subscribed for a day camp for consumptives and from thirty to forty individuals are given car fare to and from the camp and obtain scientific outdoor treatment with proper food supply under the direction of Dr. John Pryor and Dr. George Eckles on a farm tract within the city limits. The work is being carried on through the efforts of the Erie County Branch of the National Red Cross Society and the Tuberculosis Committee of the Charity Organization Society.

New York City.

Personal.—Dr. David E. Hoag will accompany the annual tour of the American Automobile Association as its official surgeon. The tour began at Buffalo July 9.——Dr. Louis F. Bishop, Dr. and Mrs. S. O. Vander Poel and Dr. and Mrs. Albert Warren Ferris have sailed for Europe.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending July 4, 472 cases of measles with 15 deaths; 374 cases of tuberculosis, with 150 deaths; 244 cases of scarlet fever, with 23 deaths; 243 cases of diphtheria, with 28 deaths; 37 cases of typhoid, with 8 deaths; 17 cases of whooping cough with 5 deaths; 54 cases of varicella and 2 deaths from cerebrospinal meningitis, a total of 1,441 cases and 231 deaths.

PENNSYLVANIA.

Philadelphia.

Fourth of July Injuries.—According to the reports of the various hospitals throughout the city, nearly 1,000 persons were injured by fireworks. Very few of the injuries sustained this year were of major importance; but one death has resulted since from tetanus.

Suspended.—At a meeting of the County Medical Society, June 17, Dr. Louis J. Lautenbach, accused of diverting patients from the Philadelphia Eye, Ear, Nose and Throat Institute, a project conducted by the doctor, to his office for treatment, was found guilty and suspended for two years. A motion was also adopted recommending to the State Board of Public Charities that the charter of his institute be revoked.

Charity Society's Deficit.—According to a report of the Society for Organizing Charity, the organization will close its fiscal year this summer with a deficit of $10,000. It is claimed that the resources of the society have been exhausted by the financial depression. The following report shows the work accomplished by the society during the winter: Total applications, 11,015; number of families represented, 6,094; families under care, 1,539; permanent employment procured, 177; temporary employment, 362; employed under auspices of society, 1,097; relief to families, $18,594.73; relief for families through other agencies, 2,312; visits to poor, 29,313; individuals cared for at lodges, 12,179.

Health Report.—The total number of deaths reported for the week ended July 11, aggregated 585, including 312 males and 273 females. This is an increase of 64 over the number reported the preceding week, and an increase of 117 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid, 7; measles, 7; pertussis, 5; diphtheria, 6; consumption, 38; cancer, 26; diabetes, 4; paralysis, 12; tetanus, 2; heart disease, 41; acute respiratory disease, 28; enteritis, 113; apoplexy, 11; hepatic cirrhosis, 5; appendicitis, 8; nephritis, 37; premature birth, 9; congenital debility, 20; suicide, 6; accidents, 19; sunstroke and heat, 29; and marasmus, 9. There were 119 cases of contagious diseases, with 14 deaths, as compared with 119 cases and 20 deaths reported in the preceding week.

TENNESSEE.

Smallpox.—Dr. Philander D. Sims, city physician of Chattanooga, reports that, on June 5, there were 20 cases confined in the Isolation Hospital and that 2 other patients were under strict quarantine.

Society Meetings.—The Upper Cumberland Medical Society held its annual meeting at Sparta May 27. The following officers were elected: Dr. Byrd S. Rhea, Bon Air, president; Drs. John T. Moore, Algood, Thomas J. Potter, Smithville, and William M. Breeding, vice-presidents; Dr. Venable L. Lewis, Crossville, secretary, and Dr. R. E. Lee Smith, Doyle Station, treasurer.——At the twenty-eighth annual meeting of the Middle Tennessee Medical Association, held in Centreville, May 21 and 22, Dr. William M. Litterer, Nashville, was elected president; Dr. Leonard E. Ragsdale, Williamsport, vice-president, and Dr. R. Logan Jones, Nashville, secretary-treasurer (re-elected).——The West Tennessee Medical and Surgical Association held its annual meeting in Jackson May 21 and 22, at which the following resolutions were unanimously adopted:

> *Resolved*, That we, as members of the West Tennessee Medical and Surgical Association, will discard the use of all secret formulary products, and will decline to use proprietary medicines that are advertised either to the profession or to the public, through agents or otherwise, believing that as a rule, ready-made remedies are not conducive to the study of materia medica and the therapeutic action of medicines, and that such practice is contrary to rational medicine and results in routine practice without a due adaptation of remedies to diseases. We believe it to be more commendable to have a thorough knowledge of the action of a few drugs and know when and how to use them, than the careless habit of prescribing compounds, the effect of which we know but little or nothing.
>
> *Resolved*, That, believing the National Formulary contains a sufficient number of drugs and combinations to meet the various indications in the treatment of disease, that we endeavor to confine our practice to the official products contained therein. And it is the sense of this society that students in medical colleges should not attempt to pass a final examination in materia medica until they apply for a diploma at the end of the course.

The following officers were elected: President, Dr. Frank D. Smythe, Memphis; vice-presidents, Drs. Joseph R. Nelson, Eurekaton, and Lorenzo L. Webb, Carroll, and secretary-treasurer, Dr. Isaac A. McSwain, Paris.

TEXAS.

May Vital Statistics.—During May there were reported to the health department 5,111 births, with 1,768 deaths. Of the decedents, 353 were over 60 years of age and 330 under 1 year old.

Endorses Amendment to School Law.—The North Texas Medical Association, at its fifty-seventh semi-annual meeting, held in Denison June 17 and 18, adopted resolutions setting forth needed improvements in the county public school system and endorsing the pending constitutional amendment relating to public free schools. The association holds its next meeting in Dallas in December.

Tuberculosis Fight.—Dr. Hatch W. Cummins, Hearne, president of the State Medical Association of Texas, has written a letter to the councilors of the association, urging their support and help in selecting delegates to the International Meeting on Tuberculosis. He requests that each councilor furnish the names of five physicians of his district, who promise to attend, that these may be added to the list of delegates.

UTAH.

Verdict Against Physician.—In the case of Mrs. Jane James against Dr. J. E. Robertson, in which damages of $5.000 were claimed on account of alleged neglect by the physician which caused the plaintiff to lose one eye, the jury is said to have returned a verdict, June 12, for the plaintiff, assessing damages at $1,500.

Health Bulletin.—During May, 361 deaths were reported in the state. There were 94 cases of scarlet fever, with 5 deaths; 33 cases of smallpox; 35 cases of diphtheria, with 3 deaths; 27 cases of typhoid fever, with 2 deaths; 581 cases of measles, with 3 deaths; 8 cases of chickenpox; 159 cases of pneumonia, with 58 deaths, and 16 cases of tuberculosis, with 10 deaths.

Sentenced to Penitentiary.—Dr. Edward S. Payne, an aged practitioner of Salt Lake City, indicted on eight counts for sending out literature and medicine contrary to law, is said to have pleaded guilty on two counts and to have been sentenced to imprisonment for two years at hard labor in the United States penitentiary at Fort Leavenworth.

VERMONT.

Vermont Alumni Meet.—At the annual meeting of the Alumni Association of Vermont University Medical Department, Burlington, held June 23, the following officers were elected: President, Dr. W. Scott Nay, Underhill, '73; vice-presidents, Drs. U. A. Woodbury, Burlington, '59; Jacob C. Rutherford, Providence, R. I., '86; Donly C. Hawley, Burlington, '84; Matthew J. Wilson, Philadelphia, '83, and William H. Briard, Boston, '83, and secretary-treasurer, Dr. Lyman Allen, Burlington, '93.

Soo Valley Society Election.—At the thirteenth annual meeting of the Soo Valley Medical Association, held in Sioux Falls, S. D., June 19, the following officers were elected: President, Dr. Charles O. Wright, Luverne, Minn.; vice-presidents, Drs. Prince Sawyer, Sioux City, Iowa; Elwin F. Reamer, Mitchell, S. D.; secretary, Dr. Charles L. Sherman, Luverne, Minn.; treasurer, Dr. Samuel A. Brown, Sioux Falls, S. D.; and censors, Drs. Gilbert G. Cottam, Rock Rapids, Iowa; William P. Roberts, Sioux Falls, S. D.; John A. Dales, Sioux City, Iowa, and Arthur E. Cook, Randolph.

VIRGINIA.

Personal.—Drs. Horace Hoskins, Frank G. Scott, Harry F. White, and Eugene Eggleston are the newly appointed internes at the City Hospital, Richmond.——Dr. Oscar Fletcher has succeeded Dr. I. J. Roper as surgeon in charge of the King's Daughters Hospital, Norfolk.

Medical Staff Elected.—The council committee on relief of the poor of Richmond have appointed the following consulting staff for the City Home: Surgical, Drs. George Ben Johnston, Charles R. Robins, H. Stuart MacLean, and James W. Henson; medical, Drs. William S. Gordon, McGuire Newton, Manfred Call, and John G. Trevilian, and eye and ear, Drs. Joseph A. White and Clifton M. Miller.

Elections.—At the meeting of the Alumni Association of the Medical College of Virginia, the following officers were elected: President. Dr. William C. Barker, Buchanan; vice-presidents, Drs. W. E. Evans, Noland, N. C.; L. A. Burke, Petersburg, and H. B. Mahood, Emporia; secretary, Dr. McCaw Tompkins, Richmond; assistant secretary, Dr. D. D. Talley, Jr., Richmond, and treasurer, Dr. Frank H. Beadles. Richmond.——The thirteenth semi-annual meeting of the Southwest Virginia Medical Association was held in Emporia. June 2, when the following officers were elected: President, Dr. Peyton B. Green, Wytheville; vice-presidents, Drs. Thomas D. Hutton, Glade Spring, and James H. Dunkley, Saltville, and secretary-treasurer, Dr. A. B. Greiner, Rural Retreat.

Report of the Smallpox Epidemic in Alexandria.—Passed Assistant Surgeon Goldberger, in his official report to the surgeon-general of the U. S. Public Health and Marine-Hospital Service, states that cases of this disease had been occurring from time to time since early in January of this year, but on account of its mildness many of the laity had questioned the correctness of the health officer's diagnosis, and had accordingly been indifferent or actively opposed to taking the necessary sanitary measures for its suppression. In 13 cases of the disease in six families, 4 presented a well-marked discrete eruption which was clearly that of smallpox; the others were convalescent, evidently from the same disease. With only one exception, none claimed to have ever been vaccinated, although several were children of school age; the one exception was a young man presenting a well-marked discrete eruption who claimed to have been vaccinated in 1898, but a careful search for a scar failed to reveal any evidence of it. Practically nothing is being done to suppress the disease. The health officer stated that disinfection with formaldehyd was being practiced, but from his description of the method employed Dr. Goldberger believes that it is ineffective. There being no hospital where the sick and contacts can be taken for treatment and isolation, an attempt was made to isolate them in their homes by placing a guard outside. This guard was maintained during the day only. Manifestly this practice affords little, if any, protection to the community; on the contrary, by permitting a continuance of the intimate association in the household between the sick and the well (the latter, for the most part, unprotected children), there is a condition of affairs which is in the highest degree favorable to the multiplication in the number of cases and the indefinite prolongation of the outbreak.

WEST VIRGINIA.

Personal.—Dr. Daniel J. Rudasill, Kingwood, has been appointed local U. S. pension examining surgeon.——Dr. Stewart, Wheeling, who has been physician for the penitentiary for several years, has resigned.

State Society Meetings.—The forty-first annual meeting of the West Virginia State Medical Association was held in Clarksburg, May 13-15, under the presidency of Dr. William W. Golden, Elkins. The following officers were elected: President, Dr. Fleming Howell, Clarksburg; president-elect, Dr. Vincent T. Churchman, Charleston; vice-presidents, Drs. Robert J. Reed, Wheeling; Rawley H. Powell, Grafton, and Henry D. Hatfield, Eckman; secretary, Dr. Thomas W. Moore, Huntington; treasurer, Dr. Timothy L. Barber, Charleston; councilors, first district, Drs. Henry P. Linsz, Wheeling, and Arthur O. Flowers, Clarksburg; second district, Drs. Richard E. Venning, Charleston, and John C. Irons, Elkins; third district, Drs. Peter A. Haley, Charleston, and George D. Lind, New Richmond; fourth district, Drs. Thomas J. McGuire and William N. Burwell, Parkersburg; fifth district, Drs. Joseph B. Kirk, Elkhorn, and Joseph E. Rader, Huntington; delegate to the American Medical Association, Dr. J. G. Walden, Wheeling, and alternate, Dr. Orra F. Covert, Moundsville. The next meeting of the association will be held in Elkins. In his presidential address Dr. Howell advocated the conversion of one of the state's hospitals for the insane into a detention sanatorium. The following resolution, introduced by Dr. Alva S. Grimm, St. Marys, was adopted:

> WHEREAS, The study of alcohol from a scientific standpoint has demonstrated that its action is deceptive and that it does not have the medical properties that we once claimed for it, now, therefore, be it
>
> *Resolved*, By the West Virginia State Medical Association, That we deplore the fact that our profession has been quoted so long as claiming for it virtues which it does not possess, and that we earnestly pledge ourselves to discourage the use of it, both in and out of the sick room.

GENERAL.

Examination of Rats.—Passed Assistant Surgeon Currie reports that, during the week ended May 30, 475 rats were trapped in Honolulu and destroyed, but none was found infected.

Yellow Fever.—Acting Assistant Surgeon Wilson reports from Santiago that a case of yellow fever was reported in that city, June 4. in a Spaniard who died seven days later. The autopsy verified the diagnosis.

Dock Goes to Tulane.—Dr. George Dock, professor of theory and practice of medicine in the University of Michigan; a well-known writer and investigator in pathology and clinical medicine, has accepted the chair of the theory and practice of medicine, and clinical medicine in the Medical Department of Tulane University, Louisiana.

Coming Meetings.—The American Academy of Ophthalmology and Oto-Laryngology will hold its annual meeting in Cleveland, August 27-29, with headquarters at the Hollenden Hotel. Dr. Secord H. Large is chairman of the committee of arrangements.——The annual meeting of the Medical Association of the Southwest will be held in Kansas City, October 20 and 21. Dr. John Punton is chairman of the committee of arrangements.

Marine Hospital Posts Open.—The Public Health and Marine-Hospital Service announces an examination at 3 B Street S.-E., Washington, D. C., Monday, Sept. 14, 1908, for assistant surgeons. Candidates must be between 22 and 30 years of age, graduates of reputable medical colleges, and free from any ailment which would disqualify them for service in any climate. The terms of service, etc., have been described in The Journal, or may be obtained on application to the surgeon-general at the above address.

The Southern Medical Journal.—The first number of this new medical journal, having Nashville, Tenn., for its place of publication, is very attractive. We are informed that "no 'hobby' or 'scheme' of any individual school or locality is promoted, and no advertisements of questionable character appear in it." The present issue, which is well printed on paper of good quality, contains a variety of excellent original articles besides editorial articles, abstracts of current literature, etc. The policy laid down for the journal by its promoters is clean, explicit, and courageous, and we wish it a hearty success.

International Congress on Tuberculosis.—Within the last few days Dr. John S. Fulton, the secretary-general of the International Congress on Tuberculosis to be held in Washington, D. C., Sept. 21-Oct. 12, 1908, has been notified of the formation of a committee of arrangements for Cape Colony in South Africa; and of the appointment of official delegates by the departments of state of Denmark, Spain, Newfoundland, Russia, England, Scotland and France. The chairman of the South African Committee is Dr. A. Jasper Anderson, Cape Town, medical officer of health for that district, and chairman of the council of the Association for the Prevention of Consumption and of Other Forms of Tuberculosis in Cape Colony. The committee includes, in addition to a number of representative physicians and laymen, the Rev. A. P. Bender, rabbi of the synagogue at Cape Town. The official delegates from Denmark are Prof. B. Bang, Professor Fibiger and Dr. H. Rördam, a military surgeon and a member of the Danish parliament. Dr. Bang will deliver a lecture during the congress on the method of immunization of cattle which has been adopted by the Danish government and which bears his name. The Bang method has attracted favorable attention in the United States and is being tried by some dairymen. The system is a welcome substitute for the plan of killing all infected cattle. Instead of resorting to extreme measures, tuberculous cows are not required to be disposed of, but are separated from the main herd. The calves of these animals are removed from the infected herd; are carefully fed on sterilized milk; and if results justify it, are finally placed with the healthy herd. In this way the healthy herd gradually increases in size and the diseased one runs out. Dr. Camilo Calleja, Madrid, the Spanish official delegate, is a writer on scientific topics, and is the author of a number of well-known works. Dr. Ramon y. Cajal, Madrid, the winner of the Nobel Prize awarded in 1906, is a member of the Spanish committee of arrangements for the congress. The French official delegates reported so far include Prof. L. Landouzy of the Faculty of Medicine at the University of Paris, the president of the French committee of arrangements for the congress; M. Leune, inspector of the academy, who will represent the Department of Public Instruction of France; and Dr. Maurice Mignon, Nice, who will come from the Mediterranean Medical Society. Dr. S. S. Steriopulo, Moscow, will come as a delegate of the permanent Russian Tuberculosis Commission, and Mr. K. J. Kalning of Riga will represent the Baltic Veterinary Society. Dr. Henry G. Beyer, chairman of the committee on the exhibition to be held in connection with the congress, has been notified of the arrival in this country of the exhibits which have been assembled by the national committees of Germany, Sweden and Switzerland. The New National Museum in which the congress and the exhibition are to be housed, will not be finished by the time the congress convenes. The first and second floors, however, will be put into such a state as to house the congress and the exhibits conveniently. These two floors have a combined space of about 100,000 square feet. The use of this building was authorized by Congress, and $40,000 was appropriated to make it available for the meeting and to accommodate the exhibits.

FOREIGN.

Transactions of International Hygiene Congress.—The four volumes containing the official transactions of the Fourteenth International Congress for Hygiene and Demography, held at Berlin last September, are published by August Hirschwald, Unter den Linden 68, Berlin. The volumes can be bought separately at prices ranging from $1.50 to $5, or the whole set is sold for $12.50.

Cholera in India.—Consul-General Michael reports from Calcutta that the work of inoculation against cholera in the coal fields is being pushed vigorously. Dr. Haffkine spent a day in Asansol for the purpose of meeting the residents with a view to affording those who wished the opportunity of protecting themselves. He has arranged to carry on inoculation at the Chota Nagpur and vicinity. The present epidemic has reawakened interest in cholera inoculation, which was carried on extensively and with a large measure of success between 1893 and 1896, and which, though continued for some years afterward, was completely overshadowed by the outbreak of plague.

Personal.—Dr. Samuel Gemmel, professor of clinical medicine in the University of Glasgow, has been appointed professor of practice of medicine in that institution to succeed the late Sir Thomas McCall Anderson.——The following medical men were among the recipients of "birthday honors" in Great Britain: Sir Thomas Lauder Brunton and Prof. Watson Cheyne have been created baronets; Col. David Bruce of the royal army medical corps, Mr. Robert W. Burnet and Mr. Peter O'Connell have been knighted; William Henry Power, C.B., has been promoted to knight commander of the Order of the Bath; Lieut.-Col. Francis F. Perry, Indian Medical Service, principal of the Medical College of Lahore, has been made a Companion of the Indian Empire; and Lieut.-Col. Johnston Shearer of the Indian Medical Service has been made a Companion of the Order of the Bath.

LONDON LETTER.

(From Our Regular Correspondent.)

London, June 27, 1908.

The Research Defense Society.

The inaugural meeting of this society, formed "to make known generally the facts about experiments on animals in this country," was held at the house of the Royal Society of Medicine. The president, Lord Cromer, delivered an eloquent address in defense of vivisection. He said that it had been shown that vivisection had yielded invaluable results and promised results still more invaluable. Experiments were conducted in such a way as to minimize, if not to abolish, pain. Nearly every discovery in medical science since Harvey discovered the circulation of the blood was, directly or indirectly, the result of experiments on animals. One of the greatest discoveries of modern times—transmission of malaria by mosquitoes—was going to make the tropics habitable. When Professor Osler was asked at the Royal Commission on Vivisection, now sitting, whether this discovery could have been made had it not been for previous experiments on animals, "Never" was the reply. "The men who made these investigations spent their lives in the laboratories and their whole work has been based on experiments on animals." The case of antitoxin was another example. The statistics of the Metropolitan Asylums Board of the percentage of fatal cases had sunk from 28 in the period which preceded the introduction of the antitoxin treatment to 2.8 per cent. Great misapprehension existed as to the extent to which vivisection was carried on. According to the latest figures about 73,000 experiments were made in 1907. But of these no fewer than 96.5 per cent. were inoculations, that is to say, did not involve operations of any kind. In the remaining 3.5 per cent. the operation was always carried on under an anesthetic. Speaking before the Royal Commission Professor Starling had said: "Though I have been engaged in the experimental pursuit of physiology for the last seventeen years, on no occasion have I ever seen pain inflicted in any experiment on a dog or cat, or, I might add, a rabbit in a physiologic laboratory in this country."

A Doctor in the Arctic.

Dr. James F. Rymer will shortly gain the distinction of being the first qualified British medical man to take up his residence in the Arctic Circle. After serving eight years as medical officer at the Carthusian Monastery in Sussex, Dr.

Rymer went to Canada and for the past six months has lived at Edmonton, Alberta Recently he left there on a lonely journey of 1 800 miles along the Athabasca and Mackenzie rivers his destination being Fort Good Hope which is about 100 miles within the Arctic Circle He does not propose to return to civilization for at least three years He has sufficient medicine in concentrated forms to last at least one year and has arranged for more to be forwarded His patients will be the Indians and Esquimaux in the vicinity of Fort Good Hope and Fort Macpherson Several diseases and fevers often break out among them and as they have no skilled attention the loss of life has been enormous The Doctor can speak French which is the only language other than their own which the Indians understand, and intends to start the study of the languages of the Indians and Esquimaux directly he arrives At his headquarters he will not have more than five white companions these being connected with a Roman Catholic mission and trading post

Craniologic Investigation by the Egyptian Government at the Royal College of Surgeons

The director general of the survey department of the Egyptian government has written to the Royal College of Surgeons asking that facilities may be given to Dr Elliott Smith and Dr Wood Jones of the Cairo Medical School to carry out in the museum of the college an examination of a collection of material found in the course of excavations made in the Nile Valley and representing the varied races of people who inhabited Nubia in ancient times together with their pathology and the results of their surgery The Egyptian government offers the museum of the college the material, which is sent for the purposes of comparative study The president has informed the government that the desired facilities would be granted The council of the college resolved that the government should be informed that they regarded the collection of specimens as a most valuable addition to the museum

The Dangers of Motor Traffic in London

The nuisance and dangers of the motor bus are much in evidence At a protest meeting on the subject held in the city the Lord Mayor presided Sir Dyce Duckworth, physician to St Bartholomew's Hospital, objected to the motor buses and cars on the following grounds They create a fearful noise and vibration Their speed in many places is a perpetual danger Fatal and other injuries to people and property are increasing Dropping of petrol causes slipperiness to horses and damages varnish of carriages The stench is insufferable 'In short locomotion in the streets of London has now become abominable and little short of a prolonged agony" The following are the official figures of the accidents which occurred last year Accidents caused by motor buses 4,723, fatal cases, 36, cases of personal injury, 1,068 Accidents caused by motor cars 5 959 fatal cases 66, cases of personal injury 2 055 A resolution was carried calling for amended legislation in the interests of the public and declaring the excessive noise, speed and noxious smell of a large proportion of the motor traffic to constitute a great danger

Survival After Rupture of the Spinal Cord

A remarkable case of rupture of the cervical spinal cord in which the patient survived has just been brought to a close in St Bartholomew's Hospital In last October a lad, aged 17 was crushed across the shoulders while trying to get out of an elevator His spine was broken and he was paralyzed below the neck As he could not use his arms he was unable to feed himself An operation was performed to ascertain whether bone was pressing on the spinal cord The cord was found severed two inches from the brain After lying in bed for four and one half months the boy was able to twitch his fingers but this was the only movement he ever regained He received unremitting attention and everything was done to brighten his life A special reading desk was fitted up above his bed He lived for seven and one half months

London and Counties Medical Protection Association

The annual report of the London and Counties Medical Protection Association shows that there is an increased tendency of people to claim compensation from doctors when the results of treatment are not as satisfactory as could be wished and to make this fact a ground for not paying their bills Thus a member who took proceedings to recover fees for medical attendance was met by a counter claim for $250 on the ground of alleged negligence and want of skill The case was defended by the society The judge gave judgment for the plaintiff and said that the counter claim was monstrous The question whether the society should not only pay the expense of defending actions against its members (as it does now) but also undertake to reimburse members for adverse verdicts and costs has been under consideration To do so it would be necessary to raise the annual subscription from $2 50 to $5 A circular was issued to the members of the society requesting them to vote on the project The result was very unsatisfactory Two thirds of the members did not vote and of those who did four fifths were in favor of the scheme The council was therefore unable to move any farther in the matter

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, June 15 1908

An Antiquackery Bill

That folly and the quackery which feeds on it, flourishes not only in the land of freedom under a republican system but also in monarchies, even in states with an absolute government is a fact with which we must reckon and all regulations which have been devised or which can be thought of will not alter this fact Neither legal restrictions nor education of the people, from which so much is expected at present, will banish quackery from the world This conviction, however must not hinder us from continually seeking new methods for repressing this evil which injures the sick, not only in purse but often in life and limb In this direction a duty is especially imposed on physicians We do not wish to deny that in this matter we are contending for our own interests—on the contrary we may freely acknowledge that we do not patiently put up with an injury to our material interests but are seeking to carry on a justifiable struggle for our means of livelihood But this struggle on the part of physicians is justified in the eyes of the public by the fact that it is carried on also to an equal extent or in a higher degree, in the interest of the community and especially of its weaker part, those who are sick and suffering

It may be already known to you that in Germany up to the year 1869 there was a legal prohibition of quackery This was abolished not on the initiative of the government, but on that of the liberal party, which in its idealism was of the opinion that the German people were well enough educated always to prefer scientific physicians to quacks To be sure, under these restrictive measures quackery prevailed to a not inconsiderable extent, but it must be admitted, on the other hand that since the removal of the prohibition quackery has grown markedly in extent and in pernicious activity

According to an official report for the year 1901, quackery has increased in Berlin 1600 per cent in the last twenty years, and according to approximate statistics of the same year the number of professional quacks in Germany was 12 000 According to a compilation by Dr Reissig, from 1888 to 1891, there were sold in Germany 1 724 000 books by quack authors, at a price of 14 500,000 marks ($3,480,000) The sort of persons who make a business of treating the sick without a medical license has frequently been publicly established Not only people of the most inferior education, but also persons of the lowest ethical standing, who have repeatedly been punished with imprisonment or sent to the house of correction, possess the confidence of the public to such an extent that care for the health is entrusted to them To be sure the attempt has been made by police regulations and by instruction of the public to restrict quackery Quacks have often been punished for violation of the sections of the law regarding injury to health and homicide by carelessness, and yet no recession of quackery has been observed The material advantages which can be secured in this convenient way—convenient at a time when newspaper information is very widespread and everything which is printed is believed, not simply by the uneducated—are so enticing that the business is carried on boldly in spite of all threatened punishments and is constantly being taken up anew by still other people On account of these facts the government as I have already mentioned in a former letter, has determined to limit quackery or, as it is termed the exercise of the healing art by unapproved (*nicht approbierte*) persons, by a special law A law entirely prohibiting quackery is not contemplated by the government, chiefly because the prospect of such a law being accepted by the reichstag is very small The radical (*freisinnige*) party would vote against it on the same ground as that on which their predecessors supported the abolition of the prohibition of quackery namely from ideal principles from their policy to leave every citizen as much freedom as possible The social democrats are op posed to it, because the majority of quacks belong to the lowest of the population, from which that party draws most of its adherents, and similar reasons would be influential with the other parties in bringing about the defeat of a law which contained a prohibition of quackery. The bill which the government published a few months ago, in order to obtain the opinions of the classes interested, contemplates placing the quacks under the strictest control so that they will be obliged to keep record books in which statements of their business shall be regularly entered. The so-called absent treatment (by letter, etc.), treatment of venereal diseases, and treatment by means of hypnosis and narcosis or by means of so-called mystical methods (magnetism, spiritualism, etc.), are forbidden. If the quack is convicted of a punishable offense in the exercise of his "profession" he may be forbidden to practice it. Whoever makes untrue statements in public advertisements regarding the treatment of the sick or remedies therefor is liable to punishment. These are the essential provisions. The German medical profession has expressed itself favorable to this bill in the professional press, and in some cases demanded stricter provisions. The German Medical Convention, which meets at the end of June, and which is composed of delegates who represent the majority of the organized physicians, will take up the question with the same intent. From the public, and especially from the parliamentary class, no considerable number of opinions regarding the bill have so far found expression. It is easy to understand that the quacks themselves, especially so far as they are organized in associations, vigorously oppose it. Whether the government will have the courage actually to introduce a bill into the reichstag and what success it will have, remains to be seen. In view of the composition of our reichstag, too great hopes are, unfortunately, not to be indulged in.

Value of Diphtheria Antitoxin.

While in your country certain states are already furnishing diphtheria antitoxin gratis to physicians (in a similar manner as the Italian government supplies its physicians with quinin for the fight against malaria), there are still in Germany, in the country where diphtheria antitoxin originated, a number of physicians who are not yet convinced of the effectiveness of the serum and who do not use it in their practice. They are supported by certain prominent medical statisticians who, on the ground of epidemiologic studies, sustain the view that the undoubted diminution in diphtheria mortality for the last fifteen years is to be referred to the natural variation of the so-called *genus epidemicus*, and that the antitoxin has had no share in this diminution of the death rate. Most practitioners, indeed, and particularly all pediatrists (in Austria, Prof. Kassowitz forms perhaps the only exception), are unconditional supporters of antitoxin. This position found expression in an address which the renowned Berlin pediatrist, A. Baginsky, delivered before the Berlin Medical Society, June 17. The speaker, as well as the pediatrists and surgeons who followed him, emphasized the importance of the antitoxin treatment. The fact that the diphtheria mortality in the hospitals has sunk from about 40 to 50 per cent. before the discovery of antitoxin to the present figure of 10 to 20 per cent., and that the death rate of tracheotomy cases which before the year 1894 was about 70 per cent. now reaches only about 20 per cent., is unconditionally attributed to antitoxin, and it was urged on physicians as a duty by all the speakers to employ the serum at the right time in every case of diphtheria. In Germany from 4,000 to 5,000 antitoxin units are injected as a maximum, while in America (as was repeatedly recalled in the discussion) in severe cases as much as 20,000 to 30,000 units are injected. Whether it is possible to lower the present mortality figures by the use of these large doses, further experience must decide.

Professor Behring.

While the antitoxin treatment of diphtheria is almost universally accepted in the entire civilized world, it is unfortunate that we can not report anything very encouraging regarding the health of its discoverer, E. Behring. To be sure the reports of a mental affliction or of progressive paralysis—which emanated from Paris and may well be called malicious—have fortunately not been confirmed; but for a number of months he has been in a sanatorium for nervous diseases at Munich, undergoing treatment for his marked neurasthenia. The extraordinarily exhaustive intellectual labor, the numerous severe disappointments which this too sanguine man has experienced in his various fields of work and especially in tuberculosis, the not inconsiderable material responsibilities necessitated by his establishment at Marburg planned on an unusually large scale (where he has spent several hundred thousand marks in organizing the business of his investigations, and especially in the search for a remedy against tuberculosis), and probably still other causes have made severe demands on the elastic force of this laborious investigator and produced a certain degree of exhaustion. It is to be hoped that he may again recover his previous health and continue his researches in the service of science.

VIENNA LETTER.

(*From Our Regular Correspondent.*)

Vienna, June 25, 1908.

Accidental Infection with Glanders.

An unusual accident occurred recently in the public institute for the examination of food at Czernowitz. Dr. Luksch, the chief bacteriologist, while making some investigations on the *Bacillus mallei* put a large quantity of the bacilli, obtained from an animal from the slaughter-house, into a centrifuge. The tube containing the glanders bacillus burst and the contents were scattered over the laboratory. The fragments of glass were picked up by some of the persons working in the room, and, as it was believed that the bacilli were dead or inert, no great precautions were taken to prevent infection. In the course of a few days all those who were in the room at the time of the accident, developed symptoms of glanders, especially of the tracheal and pulmonary type, and two of the victims died within forty-eight hours of the onset of the disease. Dr. Luksch also fell ill but soon recovered; two days after apparent recovery he again developed some pustules on the ear and was brought to the serotherapeutic institute in Vienna.

An Accident Hospital.

In order to centralize the teaching of accident surgery the ministry for education has arranged with the two surgical clinics of the general hospital to convert certain wards into a special accident department. The ambulance corps, as well as the police, have been instructed to deliver, after October 1, all cases requiring hospital treatment to this department. The two clinics of von Eiselsberg and Hochenegg will draw their material from it and special classes for students, both undergraduates and postgraduates, will be arranged, each group having to serve a term of fourteen days, several times a year, in the casualty ward. Part of the ward will be at the disposal of the military authorities who will institute special classes for the army military corps.

Proposed Reform in Sanitary Regulations.

A bill is before the Austrian parliament dealing with needed reforms in the sanitary regulations. The main points of the bill are: Completion of the scientific institutions, already erected, according to modern medical knowledge; centralization of all sanitary boards and the election of competent medical men as presidents of the local branches of the board; the erection of all such institutions as are required for the study and relief of disease; improvement of the position of the public health officers and larger powers for them (hitherto medical opinions have been overruled by the bureaucrats). The bill is strongly supported by the medical profession.

Professor Meyer Asked Not to Leave Vienna.

Prof. Hans Horst Meyer, the pharmacologist, who was called to Vienna about three years ago, has been asked by the senate of the Berlin University to accept the chair of pharmacology in that institution. In order to dissuade him from accepting this flattering offer a deputation of ten of the most eminent members of the profession, all professors of the Vienna medical faculty, waited on him and asked him not to desert Vienna, both for scientific and national reasons. This unusual act not only caused a widespread sensation in the profession, but also reminded the government that it is its duty to retain such eminent men at any cost. Professor Meyer will not leave Vienna.

Mortality from Tuberculosis in Austria.

The population of Austria-Hungary is about 45,000,000, and the annual mortality from tuberculosis is 750,000, or 14 per cent. of the total deaths from all causes. The northern parts of the empire show a ratio of 38 to 48 per 10,000 inhabitants, while the southern parts have only about 22 to 30 deaths from tuberculosis to each 10,000 inhabitants. The highest mortality is found in Bohemia with a mean of 54 in the north and 36 in the south, per 10,000. Vienna also has a high average mortality from this disease—42 per 10,000—but the hospitals as a center for a large area, are largely responsible for this high rate.

Pharmacology

THE BROADER AIMS OF THE COUNCIL ON PHARMACY AND CHEMISTRY.

TORALD SOLLMANN, M.D.
Member of the Council, Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University.
CLEVELAND, OHIO.

(Continued from page 140.)

XVII. THE NON-PROPRIETARY UNOFFICIAL ARTICLES.

Another problem which has caused the Council some perplexity is that regarding the unofficial substances which have somehow escaped appropriation by proprietary manufacturing houses. There is the host of non-proprietary compound formulas, ranging from morphin-atropin tablets to Dr. X.'s favorite antigout pill or pneumonia mixture. With these the Council need not at present concern itself. Their ingredients are official substances; the combinations may be desirable or, more commonly, undesirable, according to the circumstances, which were discussed in the last chapter.

There are, however, many non-proprietary simple substances, chemicals, active principles, plants, etc. (such as digitalein, cholesterin, mercury salicylate and zinc permanganate), which are not in the Pharmacopeia, and which can not easily be made the subjects of monopoly. Their number is considerable, as a glance at Merck's index or at the fluidextract list of any manufacturing house will show. They have not been admitted into the Pharmacopeia, either because they are of little or no value and little used, or because they are too new. The majority belong to the former class; they might well be spared from the materia medica. Unfortunately, however, some enthusiast periodically resurrects one or the other of them; this then springs into sudden prominence, and becomes to all intents a "new" remedy. The physician who is impressed by these reports naturally desires some unbiased and reliable information about them, as well as about the remedies which are actually new. The ordinary reference books, however, give but very scanty data; they necessarily lack the elasticity which is essential for the proper presentation of a new subject. Above all, however, a physician who desires to try these new remedies should be assured that they are of a uniform quality; but with them, there are no established standards of any kind.

A variety of abuses naturally results. The enthusiastic, if disinterested, statements of the discoverers, or re-discoverers, are rarely subjected to that serious criticism which is indispensable for scientific progress. Incalculable harm may thus be done by extensive experimentation with a remedy in conditions in which it is not indicated. On the other hand, a really valuable agent may lie neglected because no one is paid to "push" it; or it may be seized on by a proprietor, "protected" by a coined name or disguised in a mixture, and sold at an exorbitant price, under doubly exaggerated claims, as happened with phenolphthalein. Most serious of all, the uncertain quality or loose nomenclature of these drugs may constitute a very serious danger, as in the case of the digitalis principles; or at least such may cause creditable remedies to fall into disuse.

It has seemed to the Council, therefore, that there is a very real need for the collection of authoritative data about the more important or commonly used of these non proprietary unofficial articles, and a special committee has been appointed for the purpose. A list of some eighty of these substances is under discussion, and the Council will appreciate suggestions from the profession as to what substances should be included. It is not intended to confine this investigation to those articles which the Council believes to be really valuable, but also to present the facts about those which have an unjustified popularity.

When it has been decided what substances should be taken up, the necessary data will be obtained as rapidly as possible. An abstract will probably be published in these columns, and a description, prepared on the general plan of the New and Non-Official Remedies, will be inserted in a proposed book. If, then, a physician desires to obtain these drugs of standard quality, he need only affix "N. N.-O. R." to the name of the product. In the event that the drugs on the market are generally below this standard, the Council may mention the names of those manufacturers who have been found to supply the products of the required grade.

(To be continued.)

MARIENBAD TABLETS.

The Commercial Value of a Name.

What potentialities exist in a name! The great watering places and health resorts of Europe are household words and their names compel attention. Hence, when a physician receives in his mail a package bearing a foreign postmark and an unusual looking stamp, with the name "Marienbad" on the enclosure, he may possibly restrain his first impulse, born of experience, to throw the "sample" into the waste basket. He may be excused for expecting to find something of unusual merit in a medicine elaborated at such a world-renowned health resort as Marienbad. Especially is his enthusiastic expectancy pardonable when he learns that "Marienbad Tablets" are "prepared according to the prescription" of an individual with the imposing cognomen, "Prof. Dr. Med. Chevalier de Basch."

Then, too, accompanying the "sample" is a circular descriptive of the virtues of this great medicine, printed in parallel columns of massive German and picturesque English. In it he is informed that the "Marienbad Tablets act mildly, without pain on the bowels, and consequently effect their evacuation." Great stress is laid on the advantage of the "tablet-shape" which makes possible the "offering of a perfectly equal dose of the efficacious ingredients" and simplifies the administration "on account of their compendious shape." "Marienbad Tablets," he is told, are unexcelled for the treatment of that condition recognized by all physicians as "sanguiness and its after-effects, such as vergitiousness," and they are highly recommended in cases of "arteriosclerose." As a sop to Cerberus, the circular suggests "the diagnosis should be made by the physician," the assumption being that the proprietors of "Marienbad Tablets" will take care of the treatment while the prognosis will naturally take care of itself.

And the composition of this "compendious" cure for "sanguiness" and "vergitiousness"? Well, if carefully looked for, *the physician will find that "Marienbad Tablets" consist of* extract of aloes, powdered rhubarb, podophyllin, extract of cascara sagrada and extract of belladonna. That is all; just a simple cathartic tablet such as physicians are prescribing for their patients daily. They do not even contain a picturesque, pharmacologic nonentity like cactin or "latalia rad." Wherein, then, lies the special virtue of their "efficacious ingredients"? We are forced to the conclusion that this must reside in the psychic effect produced by taking a silver-coated tablet from a gilt-trimmed box, labelled "Marienbad," rather than in the essential contents of the tablets themselves.

Frederick Stearns & Co., "Patent Medicine" Vendors.

Physicians who attended the Chicago session of the American Medical Association doubtless noticed while riding on the street cars the blatant advertisements of the headache remedy SHAC (Stearns Head Ache Cure). This nostrum, which seems to have been responsible for at least two cases of poisoning,[1] is put on the market by Frederick Stearns & Co., Detroit—a fact that was noted in these pages a few months ago.[2] It was not unnaturally assumed that these Peruna-like advertising tactics had been adopted by an enterprising local representative anxious to make a "showing." The June issue of the *New Idea* —a monthly journal published by Frederick Stearns & Co. and devoted to advertising their products to retail druggists—shows that this assumption was not well founded. In their journal they inform the druggist that "a new series of SHAC street car cards are now ready for use in the large cities."

---

[1] The Journal A. M. A., Dec. 15, 1906, 2012, and Nov. 16, 1907, 1675.

The evils of the indiscriminate use by the public of such powerful and insidious drugs as are contained in the various headache remedies need no further iteration. The question has long since ceased to be an academic one and no casuistic reasoning nor specious arguments can hide the fact that enormous harm is being done by the exploitation of these acetanilid-containing nostrums, and the medical profession has expressed itself in no uncertain tone regarding the matter.

SHAC, however, is not the only "patent medicine" put on the market by Frederick Stearns & Co. Just as extensively advertised—and in the same mediums, the street cars—are Zymole Trokeys "for husky throats." Then there is Pam for the dyspeptic, a "tiny tablet of wonderful power," of which the modest statement is made that "every ferment of the digestive tract that is available is used in these tablets, fitting them for use in all kinds of indigestion." Surely, with such drugs at their command, dyspepsia need give physicians no further cause for worry!

These are some of the products put on the market by Frederick Stearns & Co. and vigorously "pushed" by them in advertisements to the laity. A firm which, while soliciting the patronage of physicians through the pages of medical journals, is at the same time furthering the interests of self-drugging and dangerous nostrum-taking, will be looked on with distrust and suspicion by the medical profession.

Uranalysis by Quacks.

Four young persons in Germany recently sent a vial each, according to directions, to the "urine specialist," J. Locher, who diagnoses disease from inspection of the urine. Each was informed that he had a catarrhal affection of the stomach, abdomen or throat, and each was instructed to buy a bottle of Locher's remedy, costing $1. They did not buy the remedy, as the vials they sent had contained nothing but diluted beer.

Book Notices

THE HARVEY LECTURES, Delivered Under the Auspices of the Harvey Society of New York, 1906-07. Pp. 314, with illustrations. Cloth. Price, $2.00. Philadelphia: J. B. Lippincott Co., 1908.

This volume is a monument to the success of the Harvey Society of New York, which was organized for the purpose of enabling practitioners of medicine to acquire at first hand from men engaged in research more knowledge concerning the scientific problems and principles underlying their profession. From the start these lectures have served as an inspiration, not only to those so fortunate as to be within the range of the Harvey Society, but also to those who have read the lectures in various medical journals. Their publication in a single volume will be welcomed by many, and their influence will be in this way extended. The benefits of such lectures as those of the Harvey Society and the various lecture associations and endowed lectureships are by no means one-sided. It often has happened that an investigator has been getting lost in the details and ramifications of his problem, when, suddenly called on to present the gist of his results in a semi-popular way, he has been obliged to look over his ground from an entirely new point of view, which has made visible new and straighter paths, or disclosed early strayings and blunders. In making his explorations clear to the uninitiated, the investigator often illuminates some dark part of the road for himself. The scope of this second series of lectures of the Harvey Society is shown by the titles and the lecturers, which we quote below. Some of them appeared in THE JOURNAL, in which case they are followed by the date of the issue in which they appeared. "The Principles of Vaccine Therapy," by Sir A. E. Wright (Aug. 10, 1907); "Bacteriologic Infections of the Digestive Tract and the Intoxications Arising Therefrom," by C. A. Herter (March 23, 1907); "Vasomotor Relations," by W. T. Porter; "The Myelins and Potential Fluid Crystals of the Body," by J. G. Adami (Feb. 9, 1907); "The Factors of Safety in Animal Structure and Animal Economy," by S. J. Meltzer (Feb. 23, 1907) "Metabolism During Inanition," by F. G. Benedict; "Recent Studies of Heredity," by E. B. Wilson (May 11, 1907); "Variations in the Genitourinary Tract," by G. S. Huntington; "Changes in the Lymphoid Tissue in Certain of the Infectious Diseases," by W. T. Councilman (March 30, 1907); "Nervous Disorders of the Heart," by Friedrich Müller; "Problems of Sanitation," by Edwin O. Jordan (Feb. 15, 1908). These lectures are all excellent and valuable. Every physician who reads Dr. Meltzer's clarifying discussion of the factors of safety, by which the body is spared from harm through accident and disease, will have an insight into physiologic pathology that will greatly help his judgment in considering every case of disease and accident he confronts.

PIROPLASMA CANIS AND ITS LIFE CYCLE IN THE TICK. By Captain S. R. Christophers, M.B., I.M.S., No. 29 of the Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. Paper. Pp. 83. Price 3s. Calcutta: Office of the Superintendent of Government Printing, India, 1907.

This is an excellent piece of investigative work showing conclusively that piroplasmosis of the dog in India is transmitted by *Rhipicephalus sanguinis* (Latreille); whereas in South Africa it is transmitted by *Hæmaphysalis leachi* (Audouin), as determined by Lounsbury. The infection is hereditary in the tick, the fact being noted that only the nymphs and adults from an infected female are infective, the larvæ not being able to produce the disease. The probable methods of evolution of the parasite in the blood are discussed, the author being of the opinion that a quotidian evolution occurs, in many cases, at least. The course of infection and the evolution of the parasite in the tick was also studied. In the gut it soon assumes the club-shaped form. This form infiltrates the body generally, including the salivary glands, and in the meantime has been changed into the spherical "zygotes," which commonly are intracellular. The latter form one or more "sporoblasts," each of which generates a rather large number of "sporozoites," this being the form inoculated into the dog by the tick. In relation to the parasite of coast fever, Koch had described long protoplasmic processes in the gut of the tick. Christophers failed to identify these forms in *Piroplasma canis*. The parasite is described as occurring in the ova of infected ticks, also in the larvæ, and its evolution during the molting process is presented. The works of Nutall and Smith, and others, on *P. canis*, and the disease it causes, is confirmed in many respects, and certain new observations are added. In addition, the general features of piroplasmosis of different animals are portrayed. Three excellent plates are included.

CLINICAL LECTURES, THIRD SERIES, THE BORDERLAND OF EPILEPSY. By Sir William R. Gowers, M.D., F.R.C.P., F.R.S., Hon-Fellow R. Coll. Phys., Ireland. Cloth. Pp. 121. Price, $1.25. Philadelphia: P. Blakiston's Son & Co., 1907.

Certain conditions more or less related to or resembling epilepsy in some of their manifestations are considered by Gowers in this volume. In cardiac syncope he sees considerable evidence of an essential identity of the process in the nerve elements with that in some epileptic conditions and that one may pass into the other in certain cases. Similarly those peculiar attacks which seem to depend on disturbance of the vagus functions, are considered by him as also sometimes on the borderland of epilepsy, and epilepsy and aural vertigo closely approach each other in some of their manifestations. In migraine, on the other hand, Gowers sees little to indicate any definite relations; though epilepsy may develop from migraine as an indirect consequence of the effect of the intense pain and associated cerebral disturbance. The disturbances of sleep, somnambulism, etc., also come under consideration in this work as borderline states, though their connection with epilepsy is not very well defined. Some forms of tic, which have been reckoned by some as associated with or allied to epileptic conditions, are not here included, but the omission is hardly important. With the description of each borderland malady some remarks on treatment have been appended, which, coming from such an authority, will be appreciated.

---

[2] THE JOURNAL A. M. A., Oct. 19, 1907, 1381.

Treatment of Diseases of Children. By G. A. Sutherland, M.D., F.R.C.P., Physician to Paddington Green Children's Hospital. Second Edition. Pp. 311. Cloth. Price, $2.00. New York: Oxford University Press, 1907.

This is a small book, necessarily superficial and therefore unsatisfactory. There is too little detail, so important in the management of infants and children. For example, only sixteen pages are devoted to the important subject of infant feeding. But while this lack of detail applies to the book as a whole, there are exceptions in certain parts of the work Considerable attention, for instance, is devoted to the apparently trivial subject of a "cold in the head," with a view to preventing the establishment of a chronic rhinitis and the development of adenoids. Apropos of the latter subject, we can not agree with the author that in a considerable number of cases operated on there is a recurrence of the growths. The "let alone" treatment of pneumonia is much to be commended, as is also the surgical treatment of empyema. We regret, however, to see no mention of the "colony" management of epilepsy. The book closes with 4 pages of "shotgun" prescriptions, always out of place in a work on pediatrics, and all the more to be regretted here when in the body of the book the author insists on diet and general measures.

Protozoa and Disease. By J. Jackson Clarke, M.D Lond., F.R.C.S., Formerly Pathologist to St. Mary's Hospital and Curator of the Museum, Demonstrator of Bacteriology, and Provisional Teacher of Biology in the Medical School. Part II. Cloth. Pp. 137, with illustrations. Price, $2.50. New York: William Wood & Co., 1908.

This is the work of an enthusiast who feels keen interest in establishing the protozoan origin of certain infectious diseases. The point of view leads inevitably to a somewhat uncritical survey of the evidence. The enormous mass of recent work on diseases known, or presumed to be due to protozoa, is only incompletely represented. We note, for example, that in the chapter on ticks no mention is made of Rickett's important papers on Rocky mountain spotted fever. Misprints of proper names, such as "Stegomeia" (p. 3), "McNeil" (p. 23) and "Levatadi" (p. 65) are not uncommon.

Nursing the Insane. By Clara Barrus, M.D., Woman Assistant Physician in the Middleton State Homeopathic Hospital, Middleton, N. Y. Cloth. Pp. 409. Price, $2.00. New York: The Macmillan Co., 1908.

The position of an attendant or nurse in an insane hospital is a peculiar one requiring not only special instruction, but also special aptitude. The first of these can be given, the latter is a natural gift. Lacking it, however, much can be done to produce fairly satisfactory attendants from well intentioned, though not specially adapted, individuals and this book includes much that is available for this purpose. The instructions are addressed particularly to women, but, as the author says, they can readily be made applicable to either sex. The information on the forms of insanity, etc., and the chapters on psychology, may seem superfluous for ordinary attendants, but their perusal will do no harm and may serve to sharpen the observing faculties.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

INCUBATION OF GELATIN AND CULTURE OF BACILLI.

Mérida, Mexico, June 19, 1908.

To the Editor:—1. Will you please inform me how Dr. Rivas is able to incubate gelatin at 37 C. without liquefaction, as is mentioned in The Journal, May 9, 1908, page 1493? It would be most interesting to know the formula of the gelatin, as the solution of that problem would be welcomed by all bacteriologists, especially those who are working in tropical countries.

2. I should also want to be assured that I rightly understand the differentiation Test No. 1 of Dr. Rivas' that the culture of bacteria behaves exactly like the uninoculated dextrose bouillon.

Harold Seidelin, M.D.

Answer.—1. Incubation of gelatin is performed with the full knowledge that it will liquefy at 37 C., but the ferments produced by bacteria act more rapidly at that temperature and liquefaction will occur more rapidly. If liquefaction has occurred at the end of the incubation period, whatever that may be, it will be shown by the fact that gelatin tubes immersed in ice water will not solidify as the control tubes will, or as tubes of culture of non-liquefying organisms, for instance *Bacillus coli communis*.

2. Dextrose bouillon cultures of *B. coli communis* and uninoculated dextrose broth as a control will give a canary color after boiling about 0.5 c.c. of it in about 5 c.c. of a 10 per cent. sodium hydroxid solution, whereas the saccharolytes will produce a magenta or purplish color with the same reagent.

MUSCULAR RE-EDUCATION IN TABES.

———, Maine, June 29, 1908.

To the Editor:—Please give me references to articles describing Fraenkel's method of re-educating the muscular system in tabes.

X. Y. Z.

Answer.—The name of the author referred to is Frenkel and not, as erroneously given in some text-books, Fraenkel. One prominent author refers to him as Fraenkel of Berlin, when, in fact, Frenkel lives at Heiden, Switzerland. The following articles may be referred to:

Frenkel, H. S.: *Münch. med. Wchnschr.*, 1890, No. 52.
Frenkel, H. S.: *Deutsch. med. Wchnschr.*, 1896.
Hatschek, R.: *Wien. klin. Rundschau*, XVIII.
Frank: Mistakes in the Exercise Treatment of Tabes and Their Consequences, *Wien. klin. Wchnschr.*, xvi, 42; abst. in The Journal A. M. A., Jan. 23, 1904, p. 278.
Frenkel, H. S.: Principles of Exercise Treatment of Tabes, *Berl. klin. Wchnschr.*, xlii, 23, abst. in The Journal A. M. A., July 22, 1905.

THE MORO TUBERCULIN TEST.

Pasadena, Cal., June 30, 1908.

To the Editor:—Please give references to literature on the Moro method of percutaneous introduction of tuberculin for diagnostic purposes.

Josephine A. Jackson.

Answer.—Moro, E.: Diagnostic Cutaneous Reaction After Rubbing with Tuberculin Salve, *Münch. med. Wchnschr.*, Feb. 4, 1908; abstracted in The Journal, March 14, 1908, p. 924.
Lignieres and Benjamin, H.: Specific Reaction to Tuberculin Rubbed into Shaved Skin. *Bull. de l'Acad. de méd.*, Feb. 18, 1908.
Heinemann, H.: Harmlessness and Superiority of the Tuberculin Salve Reaction Over the Ocular Reaction, *Münch. med. Wchnschr.*, March 17, 1908.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending July 11, 1908:

Bingham, E. G., capt., M. C., relieved from duty at Army Gen. Hospital, San Francisco, and ordered to Ft. Porter, N. Y., for duty.

Van Dusen, J. W., capt., M. C., granted leave of absence for one month, about October 1.

Snyder, H. McC., lieut., M. C., ordered from Army Gen. Hosp., San Francisco, Cal., to Ft. Rosecrans, Cal., for temporary duty during absence on leave, of Capt. P. W. Huntington.

Ford, J. H., capt., M. C., ordered to accompany troops from Ft. Wm. Henry Harrison, Mont., to duty at American Lake, Wash.

Dale, F. A., capt., M. C., ordered to accompany troops from Ft. Lincoln, N. D., to duty at American Lake, Wash.

Ashburn, P. M., Greenleaf, H. S., Webb, W. D., Gilchrist, H. L., Loving, R. C., Heysinger, J. D., Tefft, W. H., Culler, R. M., Humphreys, H. G., Truby, W. F., Hess, L. T., Winn, R. N., Pierson, R. H., Brown, O. G., Smith, L. L., Owen, L. J., Weed, F. W., Freeman, P. L., Wolfe, E. P, Marrow, C. E., Lyster, T. C., Snoddy, C. A., Siler, J. F., Miller, E. W., Zinke, S. G., Brown, H. L., captains, M. C., and Bruns, E. H., and Cole, C. L., lieutenants, M. C., ordered to report at Washington, D. C., for examination for promotion.

DeLaney, M. A., capt., M. C., will take station at Philadelphia, until further orders, to examine applicants for Medical Reserve Corps.

Ashburn, J. K., contract surgeon, ordered to accompany troops from Ft. Assinniboine, Mont., to duty at American Lake, Wash.

Parkman, W. E., contract surgeon, ordered to accompany troops from Ft. Missoula, Mont., to duty at American Lake, Wash.

Chambers, W. H., dental surgeon, granted leave of absence for one month.

Casaday, G. H., dent. surg., left Presidio of Monterey, Cal., and arrived at Army Gen. Hosp., San Francisco, for duty.

Navy Changes.

Changes in the Medical Corps U S Navy:

Lue, J. F., surgeon detached from the *Pennsylvania* and ordered to report before a naval retiring board at the Navy Yard, Mare Island Cal, July 10, for examination for retirement, and then, to the naval hospital at that place for treatment

Freeman, J F, P. A surgeon, detached from the Navy Yard, Boston, and ordered to the *Montana*, when commissioned

Payne, J H, P. A surgeon, detached from the Naval Recruiting Station, Cleveland, Ohio, and ordered to the Navy Yard Boston, and to additional duty in connection with fitting out the *Salem*

White, E C, asst-surgeon, ordered to the Naval Recruiting Station, Cleveland, Ohio

Hoen, W. S, P A surgeon, detached from the *California* and ordered to continue treatment at the Naval Hospital, Mare Island, Cal

McDonnell, W N, P A surgeon, detached from the *Severn* and ordered to Camp Perry, Ohio, July 5, for duty in connection with the Navy rifle team

Allen, A. H, asst surgeon Camp Columbia will proceed to Sancti Spiritus, Cuba, for [illegible] on E C White

White, E C, as[illegible] urther duty in Cuba and ordered to com[illegible] orders of May 29

Old E H H, asst surgeon, detached from the Naval Hospital, Cavite P. I, and ordered to Washington, D C, for examination for promotion and then to wait orders

Blackwell, E M, and Snyder, J. J., surgeons, commissioned surgeons from March 4, 1908

Stalnaker, P R, P A surgeon, commissioned P A surgeon from May 3, 1908

Smith, F W, asst surgeon detached from the *Wisconsin* and ordered to report to the Commander, third squadron Pacific Fleet, for duty

Koltes F X, asst surgeon detached from the *Connecticut* and ordered to report to the commander, third squadron, Pacific Fleet, for duty

Flint J, asst surgeon, detached from the *Wilmington* and ordered to the *Connecticut*

Eytinge, E J O, asst surgeon, detached from the *Concord* and ordered to the *Illinois*

Higgins, M E, asst surgeon detached from the *Illinois* and ordered to report to the Commander, Third Squadron, Pacific Fleet, for duty

Winn, C K asst surgeon detached from the *Villalobos* and ordered to the *Missouri*

Steele, J M medical inspector to be placed on the retired list Sept 18, 1908 after completion of 30 years' service, in accordance with a provision contained in the naval appropriation act of May 13 1908

Taylor, J L, P A surgeon, commissioned P A surgeon, from Dec 17, 1907

Mann, W L Jr, acting asst surgeon, appointed an acting asst-surgeon from July 1, 1908

Bishop, L W, P A surgeon detached from the Naval Recruiting Station, Indianapolis, and ordered to the Naval Recruiting Station, Denver

Fiske, C N, P A surgeon ordered to the Naval Recruiting Station Boston, and to additional duty in attendance on officers of the Navy and Marine Corps residing in Boston not otherwise provided with medical attendance

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service, during the week ended July 10, 1908:

SMALLPOX—UNITED STATES

Alabama Mobile, June 13 20 7 cases

California Los Angeles, June 13 20, 1 case, San Diego to June 13 100 cases, estimated and mainly in vicinity of the Pala Indian Reservation; San Francisco, June 13 20, 4 cases

Iowa Davenport June 1 30 3 cases, Sioux City, 2 cases

Kentucky Covington, June 20 27, 3 cases, Louisiana New Orleans June 20 27, 5 cases, 1 death

Missouri. Conway, April 20 May 24, 29 cases, Kansas City, June 20 27 1 case

Ohio Cincinnati, June 19 26, 4 cases; Dayton, June 20 27, 1 case Troy, to July 3, 28 cases

Rhode Island Pawtucket June 12, 1 case.

Tennessee Dickson, June 12, 9 cases

Texas: San Antonio Jan 20 27, 1 case

Vermont Whiting, May 5, 1 case

Washington Spokane, June 13 20 17 cases

West Virginia Moundsville, June 17 July 2, 1 case.

Wisconsin La Crosse, June 20 27, 3 cases

SMALLPOX—INSULAR

Porto Rico: Mayaguez, June 6 20, 4 cases.

SMALLPOX—FOREIGN

Canada: Halifax Jan. 13 20, 6 cases

China: Amoy (Kulangsu), April 6 May 16, present; Foochow, May 23 June 6, present; Shanghai, May 18 24, 3 deaths

Cochin China: Cholon, May 23 30, 5 cases 1 death

Ecuador: Guayaquil, May 23 30, 4 deaths.

Egypt Cairo, May 27-June 3, 6 cases 2 deaths

Germany: General, May 30 June 6, 6 cases

Java: Batavia, May 2 30, 14 cases, 1 death

Portugal: Lisbon, May 30 June 13 10 cases

Russia: Moscow, May 23 June 6, 69 cases, 27 deaths; Riga, June 6 20 5 cases; St Petersburg, May 16 June 6, 40 cases, 33 deaths

Siberia: Vladivostock, May 5-14, 1 case

Turkey: Bagdad, May 30 June 6, 20 cases, 2 deaths

PLAGUE

Chile: Antofagasta, May 24, 24 cases 2 deaths; Arica, May 27, present; Iquique, May 26 11 cases, 1 death

China: Foochow, May 30 June 6 present

Cochin China Cholon, May 23 30 5 cases, 3 deaths; Saigon, May 9 30, 16 cases 15 deaths

Ecuador: Guayaquil, May 23 30, 10 deaths.

Egypt: General, May 27-June 2, 42 cases, 16 deaths; June 3 9, 36 cases, 26 deaths; Alexandria, May 29 June 10, 5 cases, 3 deaths

Mauritius: Port Louis May 1-31, 2 cases, 2 deaths

Peru: General, May 30 June 6, 38 cases, 11 deaths; Callao, 7 cases, 2 deaths; Lima, 3 cases, 4 deaths

Straits Settlements Singapore, May 9 16, 1 death

Turkey: Bagdad, May 30 June 6 11 cases, 6 deaths.

Venezuela: Caracas, June 10 12, 5 cases, 1 death.

YELLOW FEVER—INSULAR

Porto Rico: San Juan, July 8 1 case on S S *Julia* from Santiago

YELLOW FEVER—FOREIGN.

Brazil: Manaos, May 23-30, 2 cases, 2 deaths; Para, May 30 June 6, 4 cases, 4 deaths

Cuba: Daiquiri, July 6 9, 3 cases, 1 death; Santiago, July 4, 1 case

Ecuador: Guayaquil, May 23 30 1 case

Mexico: Laguna de Terminos, June 27, 2 cases; Veracruz, July 7, 1 case, 1 death.

CHOLERA

Cochin-China: Cholon, May 23 30, 23 cases, 22 deaths; Saigon, May 9 30, 71 cases, 63 deaths

Straits Settlements Singapore, May 9 16, 2 deaths.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

A State President on the Need of Public Instruction.

In his address as president of the Utah State Medical Association, Dr. H. D. Niles of Salt Lake City, Utah, said in part:
